Abstract

In the motion control research of mobile robot, the mobile robot pose is obtained by derivation of the Kinematic model of the robot. Generally, the motion model relies simply on the data from encoder feedback. Due to cumulative error, the robot pose accuracy is relatively poor by mileage positioning with encoder. Here a new method is put forward based on data fusion of gyro sensor with the encoder data, and the robot pose accuracy is analyzed and improved.

Keywords: sensor fusion; DCM; EKF filtering

1. Introduction (Basic Measurement Unit)

The idea of pose measurement system based on the fusion is as following: firstly, build motion analysis model; then with the inertial sensor data, give the accurate pose estimation.

Hardware IMU measurement system used in this paper to achieve mini atomization of inertial measurement through the MEMS technology, the IMU module contains ITG3205 gyroscope, ADXL345 accelerometer, HMC5883L electronic compass. The sensor is connected to the microprocessor via a bus, and the microprocessor reads and writes data correction of sensors.

Gyroscope, accelerometer, compass data from these three sensors output are implemented on an I²C bus interface, the sensor run as a slave device, a microprocessor done as the master device. The system structuer is shown in Figure 1.

The MEMS sensor with 3 axes digital output angular velocity, each axis is provided with a 16bit A/D converter, built-in low-pass filter with adjustable bandwidth, shown in figure 2. The measuring range is ± 2000 °/s, and ADC output frequency can be adjust in the range of 8000HZ to 3.9HZ.
2. Analysis of DCM Algorithm

The DCM algorithm is as followings: a nonlinear correlation gyro measurement data and the direction cosine change rate of difference equations. The flow algorithm in digital system is shown in figure 4.

2.1. The kinematics analysis algorithm

The kinematics equation is

\[
\frac{dr(t)}{dt} = \omega(t) \times r(t) \tag{1}
\]

\( \omega(t) \) is the angular velocity vector. With the initial state and rotating vector, it can be:

\[
\begin{align*}
\mathbf{r}(t) &= \mathbf{r}(0) + \int_0^t \omega(x) \times r(x) \, dx \\
d\theta(t) &= \omega(x) \, dt
\end{align*} \tag{2}
\]

Where \( \mathbf{r}(0) \) is the initial vector. Furtherly, in the global coordinate system, using the method of approximate matrix, it will be

\[
\begin{align*}
\mathbf{r}_{\text{global}}(t + dt) &= \mathbf{r}_{\text{global}}(t) + \mathbf{r}_{\text{global}}(t) \times d\theta(t) \\
d\theta(t) &= \omega(t) \, dt
\end{align*} \tag{3}
\]

For error compensation of angular velocity, a modified angular velocity is introduced, which is determined by the angular velocity and its correction.

\[
\omega(t) = \omega_{\text{gyro}}(t) + \omega_{\text{cor}}(t) \tag{4}
\]

Formula (5) is the DCM update equation matrix about gyroscope.

\[
R(t + dt) = R(t) \begin{bmatrix}
1 & -d\theta_z & \quad d\theta_y \\
-d\theta_z & 1 & \quad -d\theta_x \\
d\theta_y & d\theta_x & 1
\end{bmatrix} \tag{5}
\]

Here, \( d\theta_x = \omega_x \, dt, d\theta_y = \omega_y \, dt, d\theta_z = \omega_z \, dt \)

2.2. Drift compensation

In order to calculate the Roll, Pitch, Yaw for compensation, a feedback PI controller is introduced. The controller error calculation of Roll and Pitch uses the acceleration and the electronic compass Yaw error. In our experiment, the following figure is drawn based on the sensor data by IMU sensor.
In figure 6, the movement state of three axes are given. Z axis acceleration is caused by the acceleration of gravity. In figure 7, they are three axis angular velocity.

3. The Extended Kalman Filter Algorithm

Now the encoder measuring odometry data (Odom) and the inertial measurement data (IMU) can be determined. The full state vector in the space is expressed as

$$\mathbf{x}_k = [X_k, Y_k, Z_k, \phi_k, \theta_k, \psi_k, v_k, \omega_k]^T$$  \hspace{1cm} (6)

With $\Delta t$ time, we can get

$$\begin{align*}
  v_x &= \frac{\eta}{\Delta t} N_x \\
  v_y &= \frac{\eta}{\Delta t} N_y \\
  \omega_z &= \frac{v_x - v_y}{L} \\
  v &= \omega \times L
\end{align*}$$  \hspace{1cm} (7)

Where $\eta$ is parameter of the wheel diameter and encoder. The pose after $\Delta t$ will be

$$\begin{align*}
  x_{k+1} &= \begin{pmatrix}
  X_{k+1} + v_x \cos(\psi_k) \Delta t \\
  Y_{k+1} + v_y \sin(\psi_k) \Delta t \\
  \phi_k \\
  \theta_k \\
  \psi_k + \omega_z \Delta t \\
  v_z
\end{pmatrix}
\end{align*}$$  \hspace{1cm} (8)

The EKF data integration system model is given as follows:

The extended Kalman filter with fusion of encoder and gyroscope data, the system state equation is derived:

$$\mathbf{x}_{k+1} = \Phi_k \mathbf{x}_k + \Gamma \tilde{\epsilon}_k$$  \hspace{1cm} (9)

The measurement model for encoder is

$$\mathbf{y}_{\text{odom}, k} = \mathbf{C}_{\text{odom}} \mathbf{x}_k = \begin{bmatrix} X_k \\ Y_k \\ \psi_k \\ v_k \\ \omega_k \end{bmatrix} + \epsilon_{\text{odom}, k} (d)$$  \hspace{1cm} (10)

The simplified IMU mathematical model is
\[ y_{\text{gyro},k} = C_{\text{gyro}} x_k = \begin{bmatrix} \psi_k \\ \omega_k \end{bmatrix} + e_{\text{gyro},k} \]  

(11)

Error covariance of the matrix is:

\[ R(d) = \begin{bmatrix} R_{\text{odom}}(d) & 0 \\ 0 & R_{\text{gyro}} \end{bmatrix} \]  

(12)

With above the measurement model and state transition model, using the extended Kalman filtering, the robot pose estimation can be determined. In order to validate the Kalman filter, with the above data, matlab simulation is performed.

Fig. 9. The introduction of Kalman filter wave curve

Figure 9 is the introduction of Kalman filter wave curve. The output curve gets smoothing, and angle estimation accuracy is greatly improved.

4. Conclusions

In this paper, the Kalman filtering accelerometer, gyro and the electronic compass fusion method is studied. Based on dynamic test data, the Kalman filter compensates the sensor drift, noise and other factors caused by the accelerometer, gyroscope and the electronic compass. It reduces the angle measurement error, and improves the operation accuracy. The experiment results show the effectiveness of the proposed method.
