Abstract—In order to describe the car-following behavior more actually in real traffic, an extended car-following model incorporating the headway of arbitrary number of vehicles that proceed and the relative velocity is proposed from the viewpoint of control. The stability condition of the extended model is obtained by using the linear stability theory. The modified control signals will play an effect only if the traffic is in congested state. The results of simulation are accordance with our theoretical analysis.

Keywords- car-following model; control method; arbitrary number; stability analysis

I. INTRODUCTION

Suppression of the traffic congestion has attracted much attention [1-2]. An increasing number of traffic models have been developed and empirically tested. In 1995, Bando et al.[3] proposed an optimal velocity (OV) model for characterizing the car-following behavior. We recognize the OV model as a basic model for studying the phenomena of the traffic flow. In 1999, Konishi et al. [4] proposed a coupled-map (CM) car-following model (KKH model), which introduced the version of the decentralized delayed-feedback control scheme for suppressing the traffic jam. What is worth pointing out is that Zhao and Gao [6] presented another simple strategy to suppress the congested state in the traffic system with a control signal, which incorporates the effect of velocity difference between the preceding and the considered vehicle. Some research related to the control signal is carried out [4,5].

In order to improve the model with the control signal taking into account the two velocity differences, we investigate the property of extended optimal velocity model in which a driver considers arbitrary number of vehicles that proceed with extended control method.

II. MODEL

In the paper, we extended the OV model as following

\[
\frac{dv_i(t)}{dt} = a\{V^{op}(y_{i+1}(t), y_{i+2}(t), \ldots, y_{i+n}(t)) - v_i(t)\}
\]

\[
\frac{dv_{i+1}(t)}{dt} = v_{i+1}(t) - v_i(t)
\]

\[
\frac{dv_{i+2}(t)}{dt} = v_{i+2}(t) - v_{i+1}(t)
\]

\[
\vdots
\]

\[
\frac{dv_{i+n}(t)}{dt} = v_{i+n}(t) - v_{i+n-1}(t)
\]

Where \( a > 0 \) is the sensitivity of a driver with response to the difference between the optimal and current velocities, \( v_i(t) \) is velocity of the \( i \)th vehicle at time \( t \) and

\[
y_{i+n}(t) = x_{i+n}(t) - x_{i+n-1}(t)
\]

for \( n = 1, 2, 3, \ldots, N \) are headway of the \((i+n)\)th vehicle. Vehicles are numbered such that the \((i+2)\)th vehicle precedes the second vehicle. The model with \( n = 2 \) is that proposed by Ge [12]. The extended OV function is \( V^{op}(y_{i+1}(t), y_{i+1}(t), \ldots, y_{i+n}(t)) \) represents an optimal velocity of the \( i \)th vehicle and is described as

\[
V^{op}(\bar{y}(t)) = \tanh(\bar{y}(t) - \bar{h}) + \tanh(\bar{h}')
\]

Where \( \bar{y} = \sum_{i=1}^{n} a_i y_i(t) \) which is named as the weighted headway and \( a_i \) is the weighted coefficients of \( y_i(t) \). We assume that \( a_i \) have the following properties:

1. \( a_k (k = 1, 2, 3, \ldots, N) \) decrease monotonically with increasing \( k \) and \( a_k > a_{k+1} \). As the distance between the car ahead and the considered car increases, the effect of cars ahead on the car motion decreases gradually.

2. \( \sum_{k=1}^{n} a_k = 1 \) Here we select \( a_k = 6 / 7^k (k \neq n) \) and \( a_n = 1 / 7^{n-1} \) for \( k = n \).

We suppose the desired velocity of vehicles and comprehensive distance is \( v' \) and \( y' \), so the steady state of the system can be expressed as
\[(v, y) = (v', y')^T. \quad (1)\]

III. LINEAR STABILITY ANALYSIS

We apply the linear stability theory to analyze the extended model which is described by above Eq. Let model Eq. be linearized around steady state and the linearized vehicular dynamics can be rewritten as follows:

\[
\begin{align*}
\frac{dv_i(t)}{dt} &= a(\Lambda_1 y_{i+1}^0(t)) + \Lambda_2 y_{i+2}^0(t) + \cdots + \Lambda_n y_{i+n-1}^0(t) - v_i(t) \\
\frac{dy_{i+1}^0(t)}{dt} &= v_{i+1}^0(t) - y_{i+1}^0(t) \\
\frac{dy_{i+2}^0(t)}{dt} &= v_{i+2}^0(t) - y_{i+2}^0(t) \\
\vdots \\
\frac{dy_{i+n-1}^0(t)}{dt} &= v_{i+n-1}^0(t) - y_{i+n-1}^0(t)
\end{align*}
\]

where

\[
\begin{align*}
\Lambda_1 &= \frac{\partial V(y_{i+1}(t), y_{i+2}(t), \cdots, y_{i+n-1}(t))}{\partial y_{i+1}(t)} \\
\Lambda_2 &= \frac{\partial V(y_{i+1}(t), y_{i+2}(t), \cdots, y_{i+n-1}(t))}{\partial y_{i+2}(t)} \\
&\vdots \\
\Lambda_n &= \frac{\partial V(y_{i+1}(t), y_{i+2}(t), \cdots, y_{i+n-1}(t))}{\partial y_{i+n-1}(t)} \\
v_{i+1}^0(t) &= v_i(t) - v_i^0(t), v_{i+2}^0(t) = v_i(t) - v_i^0(t), \cdots, \\
v_{i+n-1}^0(t) &= v_i(t) - v_i^0(t)
\end{align*}
\]

According to the control theory, the vehicular dynamics described by above Eq can be rewritten as a linear time-invariant system as follows:

\[
\begin{align*}
\frac{dv_i^0(t)}{dt} &= -a(\Lambda_1 y_{i+1}^0(t)) + a\Lambda_2 y_{i+2}^0(t) + \cdots + a\Lambda_n y_{i+n-1}(t) \\
\frac{dy_{i+1}^0(t)}{dt} &= \Lambda_1 y_{i+1}^0(t) \\
\frac{dy_{i+2}^0(t)}{dt} &= \Lambda_2 y_{i+2}^0(t) \\
&\vdots \\
\frac{dy_{i+n-1}^0(t)}{dt} &= \Lambda_n y_{i+n-1}^0(t)
\end{align*}
\]

Taking Laplace transformation as L, we have

\[
\begin{bmatrix}
V_i^0(s) \\
Y_{i+1}^0(s) \\
Y_{i+2}^0(s) \\
\vdots \\
Y_{i+n-1}^0(s)
\end{bmatrix} = \begin{bmatrix}
a\Lambda_1 & a\Lambda_2 & \cdots & a\Lambda_n \\
0 & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
0 & 0 & 0 & \cdots & 1
\end{bmatrix} \begin{bmatrix}
v_i^0(t) \\
y_{i+1}^0(t) \\
y_{i+2}^0(t) \\
\vdots \\
y_{i+n-1}(t)
\end{bmatrix}
\]

\[
V_i^0(s) = L(v_i^0(t)), \quad Y_{i+1}^0(s) = L(y_{i+1}^0(t)).
\]

From the above Eq we can obtain the transfer relationship

\[
V_i^0(s) = \frac{a(\Lambda_1 - \Lambda_n)}{s^2 + as + a\Lambda_1} \cdot V_{i+1}^0(s) + \frac{a(\Lambda_1 - \Lambda_n)}{s^2 + as + a\Lambda_1} \cdot V_{i+2}^0(s) + \cdots + \frac{a}{s^2 + as + a\Lambda_1} \cdot V_{i+n-1}(s)
\]

\[
\{\Lambda_1 Y_{i+1}^0(s) + \Lambda_2 Y_{i+2}^0(s) + \cdots + \Lambda_n Y_{i+n-1}(s)\}
\]

\[
V_i^0(s) = T(s) \cdot V_{i+1}^0(s)
\]

Where transfer function is

\[
\frac{a(\Lambda_1 - \Lambda_n)}{s^2 + as + a\Lambda_1}
\]

and the characteristic polynomial is

\[
d(s) = s^2 + as + a\Lambda_1.
\]

In order to keep from the traffic congestion, we should keep d(s) stable. The \(H_{\infty}\) norm of transfer function \(T(s)\) is equal to or less than 1. Through derivation we can obtain the condition

\[
a \geq 2\Lambda_1, \quad \Lambda_1 > \Lambda_n.
\]

According to the model proposed by Ge [18], traffic jams will never occur.
IV. STABILITY ANALYSIS WITH CONTROL SIGNALS

In order to effectively alleviate the traffic jams, a control signal term, $u_i(t)$, is added to vehicular dynamics described as (1) by model Eq. as follows:

$$\begin{align*}
\frac{dv_i(t)}{dt} &= a[V^{\infty}(y_{i+1}(t), y_{i+2}(t), \ldots, y_{i+n}(t)) - v_i(t)] + u_i(t) \\
- v_i(t) + u_i(t) &
\end{align*}$$

where $y_i(t)$ denotes the headway of the vehicle in front.

The extended control signals $u_i(t)$ is

$$u_i(t) = \sum_{n=1}^{\infty} a_n(y_{i+n}(t) - v_{i+n}(t))$$

Where $u_i(t)$ considers the headway of arbitrary number of successive vehicles in front, $a_n$ is the feedback gains and the same to weighted coefficient of $\dot{y}_i(t)$. Around the steady state referred to model Eq., vehicle dynamics described by Eq.(1) with control signals defined by above Eq. can be rewritten as

$$\begin{align*}
\frac{dv_i^0(t)}{dt} &= a[V^{\infty}(y_{i+1}^0(t), y_{i+2}^0(t), \ldots, y_{i+n-1}^0(t)) - v_i^0(t)] + u_i^0(t) \\
- v_i^0(t) + u_i^0(t) &
\end{align*}$$

where $u_i^0(t)$ can be changed to $u_i(t) = \sum_{n=1}^{\infty} a_n \frac{dv_i^n(t)}{dt}$.

We have the following transfer relationship as the same way to deal with the above equations:

$$V_j^0(s) = \frac{a(\Lambda_j - \Lambda_k) + (k_j - k_n)s}{s^2 + (a + k_j)s + a\Lambda_j} Y_j^0(s) + \ldots$$

$$+ \frac{a(\Lambda_{j-1} - \Lambda_k) + (k_j - k_n)s}{s^2 + (a + k_j)s + a\Lambda_j} Y_j^0(s) + \ldots$$

$$+ \frac{a\Lambda_j + k_j s}{s^2 + (a + k_j)s + a\Lambda_j} Y_j^0(s) + a \sum_{k=1}^{n} \frac{v_i^0(0)\Lambda_k}{s^2 + (a + k_j)s + a\Lambda_j} V_j^0(s)$$

Where transfer function $T'(s)$ is

$$T'(s) = T'(s) \cdot V_j^0(s)$$

The characteristic polynomial $|T'(s)|_\infty < 1$ and $|T'(s)|_\infty = \sup_{\omega \in (0, \infty)} |T'(s)| \leq 1$. We make transform as follows:

$$\sqrt{T'(j\omega) \cdot T'(-j\omega)} = \sqrt{\frac{(a(\Lambda_j - \Lambda_k) + (k_j - k_n)s)(a + k_j)s}{(a\Lambda_j - \Lambda_k)^2 + ((k_j - k_n)s)^2}} < 1.$$
initial positions and speed which are set to be
\[ x_i(0) = \sum_{j=i+1}^{N} y_j(0), \quad v_i(0) = v^\ast_i, \quad i = 1, 2, \ldots, N. \]
The vehicles run without control signals for 0 ≤ i ≤ 2000, and assuming the lead vehicle suddenly stops for 2 ≤ i ≤ 52.

It is shown that Fig.1 (a) is spatiotemporal pattern of the traffic flow in an uncontrolled system and the horizontal axis defined by \( x_i = x_i - x_1 \), which represents a distance between the first vehicle and the following one. The vertical axis notes the time. It is observed that the traffic congestion occurs in Fig. 1. The region of traffic jams decreases with time. In the following research, we will give the traffic system with the extended control method signals.

It is noted that there is only smaller oscillating by our method, compared with the new non-control system. These simulations show that the extended car-following model with the control method by considering the headway of arbitrary number of vehicles that proceed can be used to suppress the traffic congestion and the traffic system exhibits better behavior.

VI. CONCLUSIONS

This paper proposes an extended control method for suppression the traffic jam based on the pioneer work of Ge [6]. The effect of our control signal on traffic congestion is investigated. We have obtained the stability condition for our model with the corresponding control signal. The simulation shows that the car-following model considering N-front vehicles has a better effect than previous ones.

Additionally, the detailed analysis of parameters and the proper number of vehicles preceded are also our future work.
