Abstract—In this article, a new method of calculating mobility for planar kinematic chains, based on kinematic graph of mechanism and matrix theory, is put forward. We proposed a new conception of network graph of mechanism to describe kinematic chains instead of kinematic graph of mechanism. With a network graph of mechanism, the displacements of components produced by applied forces can be calculated effectively and simply. Furthermore, matrixes can be established by displacement and force equation groups. By means of analyzing the matrices, we will obtain the mobility of a mechanism with no efforts as the mobility equals to the dimension of the matrix arrived from equation groups. In addition, this new method is applied to various kinds of mechanisms in plane efficiently and correctly including the kinematic chains with passive constraints and common constraints. The method of this paper can be extended to calculate mobility of spatial mechanisms too.

Keywords—mobility calculating; network graph of mechanism; matrix analysis; displacement; planar mechanism

I. INTRODUCTION

The study on mobility calculation has been continued for more than 100 years. Various methods of mobility calculation have been put forward, and many methods were analyzed in [1] by Gogu. As early as the 19th century, Reuleaux [2] defined mechanism firstly and made a system study on kinematic pairs. And on this basis Grübler [3] puts forward the general formula of degree of freedom for simple planar chains. Crossley [4] analyzed planar link mechanisms based on Grübler’s formula, and came up with the relation between kinematic pairs and the number of bodies. But for the link mechanisms with four joints, the calculation of link number should use the method of trial and error which might make mistakes. Bagci [5] presented a general formula of mobility calculation for mechanisms of \( n \) links and \( k \) loops. The formula takes into consideration that passive constraint, common constraint and passive degrees of freedom, but its results are not correct for some mechanisms. Traditionally, the classical formula of Chebyshev–Grübler [6] is used to calculate planar mechanisms’ mobility. Obviously, the formula is convenient to obtain mobility of some simple link mechanisms. But for mechanisms of passive constraints, common constraints or passive degrees of freedom, it is not easy to judge and even gets wrong results.

Recently, further researches have been reached into the mobility of rigid mechanisms [7, 8], metamorphic mechanisms [9-12] based on screw theory which is difficult to understand. The methods using Lie group [13], Lie algebra [14] and linear transformation [15] are also complicated. Dongchao Yang came up with a simple method of mobility calculation with Jacobian [16], but the rank of coefficient matrix must be calculated by MATLAB.

A new method would be presented for mobility calculation of planar mechanisms in this paper. This method makes a new way to show the kinematic chains instead of kinematic graph of mechanism. In this case, mobility calculation turns to determine the dimension of a matrix which is brought by some simple equation groups as the dimension of the matrix equals to the mobility of mechanism.

II. NEW THEORY OF MOBILITY CALCULATION FOR PLANAR MECHANISMS

A. Conception and principles of network graph of mechanism

Kinematic graph of mechanism is a simple sketch that expresses the movement of mechanism kinematics precisely using simple lines and signs. However, the positions of components in kinematic graph need to be determined accurately and proportionally. The method of this paper only requires linking relation of components, thus a new conception of network graph of mechanism is presented for describing kinematic chains instead of kinematic graph of mechanisms, which applies to this method appropriately and simply. The details of principles of network graph of mechanism are listed as follows.
Network graph of mechanism includes elasticity links, nodes and the root. The elastic links and nodes denote bodies and pairs in kinematic chains respectively. The size of components of network graph of mechanism need not be proportional to the actual components as it has absolutely no effect on mobility.

If the bodies link to the root in kinematic graph of mechanism, the nodes between them will be canceled in network graph.

If the bodies whose joints are single in open or mixed kinematic chains, they will get two nodes in network graph of mechanism.

The relative position of two elastic links in network graph of mechanism should be horizontal, vertical or at a 45-degree angle when they linked by one node, so as to analyze simply.

B. Establish equation groups based on network graph of mechanism

For the four-bar linkage in Fig. 1a, the following will present its transformation from kinematic graph to network graph of mechanism and the process of establishing equation groups.

Based on the principles above, the horizontal line AD in Fig. 1b denotes the root of the four-bar linkage; the joints B and C are denoted as m1 and m2; the nodes A and D are canceled as the bodies 1 and 3 link to the root directly; the elastic links L1, L2, L3 denote the links 1, 2, 3 respectively.

\[
A \quad B \quad C \quad D
\]

\[
\begin{align*}
e_i &= \sqrt{x_i^2 + (x_2 + L_i)^2} - L_i \\
&= \sqrt{x_i^2 + x_2^2 + 2x_2L_i + L_i^2} - L_i \\
&= L_i \sqrt{1 + \left(\frac{x_2^2}{L_i^2} + 2x_2/L_i + \frac{L_i^2}{L_i^2} \right)} - L_i \\
&= L_i + \left(\frac{x_2^2}{L_i^2} + \frac{x_2}{L_i}ight) + \frac{L_i}{L_i}O((x_2^2 + x_2^2)/L_i^2 + 2x_2/L_i) - L_i \\
&= x_2 + \left(\frac{x_2^2}{L_i^2} + \frac{x_2}{L_i}ight) + L_iO((x_2^2 + x_2^2)/L_i^2 + 2x_2/L_i)
\end{align*}
\]

Where \(O((x_2^2 + x_2^2)/L_i^2 + 2x_2/L_i)\) is the Peano remainder.

Obviously, \((x_2^2 + x_2^2)/L_i^2\) is small compared to \(x_2\), and the Peano remainder is even smaller. Thus, all the terms above except the first one can be neglected and approximately arrive at

\[
e_i = x_2
\]

The argument of the first elastic link indicates that the elongation of elastic link is its displacement along its initial direction approximately. Similarly, there are

\[
e_2 = x_3 - x_1, \quad e_3 = x_4
\]

These three displacement equation groups can be encoded in

\[
e = Ax \quad \text{where} \quad A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}
\]

The matrix \(A\) is called displacement matrix here.

There is no doubt that the elastic links are in the range of flexibility, so Hooke’s Law (if the material is in the range of flexibility, its deformation and the force loading on it will be proportional) applies to them. Naturally

\[
y_i = k_i e_i
\]

Or, in matrix terms

\[
y = Ke \quad \text{where} \quad K = \begin{bmatrix} k_1 & 0 & 0 \\ 0 & k_2 & 0 \\ 0 & 0 & k_3 \end{bmatrix}
\]

The matrix \(K\) is called stiffness matrix here.

According to the force equilibrium on each node in horizontal and vertical direction, the equilibrium equation groups can be arrived at

Figure 1. a) Four-bar linkage. b) Network graph of four-bar linkage.
Or, in matrix terms

\[
B\mathbf{y} = \mathbf{f}
\]

where \( B = \mathbf{A}^T \). Gathering the previous steps

\[
e = \mathbf{A}x, \quad y = \mathbf{K}e, \quad B\mathbf{y} = \mathbf{f}, \quad B = \mathbf{A}^T
\]

We arrive at

\[
B\mathbf{y} = \mathbf{A}^T\mathbf{y} = \mathbf{A}^T\mathbf{Ke} = \mathbf{A}^T\mathbf{KA}x = \mathbf{f}
\]

Namely,

\[
\mathbf{S} = \mathbf{A}^T\mathbf{KA}
\]

Where

\[
\mathbf{S} = \mathbf{A}^T\mathbf{KA}
\]

\[
= \begin{bmatrix}
0 & -1 & 0 \\
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
k_1 & 0 & 0 \\
k_2 & 0 & -1 \\
k_3 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
0 & 1 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

After elementary row transformation, the matrix is

\[
\mathbf{S}' = \begin{bmatrix}
k_2 & 0 & -k_2 & 0 \\
0 & k_1 & 0 & 0 \\
0 & 0 & k_3 & 0 \\
0 & 0 & 0 & k_4
\end{bmatrix}
\]

The rank of matrix \( S \) is 3, and the dimension of null space of matrix \( S \) is \( n - r(S) = 1 \). According to Chebyshev–Gruebler’s equation for planar chains, we arrive at

\[
y_2 - f_1 = 0, \ y_1 - f_2 = 0, \ y_2 - f_3 = 0, \ y_1 - f_4 = 0
\]

\[
\text{DOF} = 3(N - 1) - 2P = 3(4 - 1) - 2 \times 4 = 1
\]

Thus, there is

\[
\text{DOF} = \text{Dim.}\{\mathbf{S}\}
\]

\( \text{Dim.}\{\mathbf{S}\} \) is the dimension of null space of matrix \( S \).

This result means that the dimension of null space of matrix \( S \) equals to its respective mobility of mechanism. It has similar result in [16] that dimension of fundamental solutions of homogeneous equation group equals to the number of active joints.

III. PROOF OF NEW THEORY BY EXAMPLES

The proof of closed kinematic chains is showed in Fig. 1 which takes a four-bar linkage as an example. Under-mentions are proof of Open kinematic chains and mixed kinematic chains.

A. Open kinematic chains

Fig. 2 shows a three-bar linkage of open kinematic chain and its corresponding network graph of mechanism.

As is showed in previous section, the displacement equation groups can be easily arrived at

\[
e_1 = x_2, \ e_2 = x_4 - x_2
\]

In matrix terms, the displacement matrix is

\[
\mathbf{A} = \begin{bmatrix}
0 & 1 & 0 & 0 \\
0 & -1 & 0 & 1
\end{bmatrix}
\]

Similarly, the stiffness matrix

\[
\mathbf{K} = \begin{bmatrix}
k_1 & 0 \\
0 & k_2
\end{bmatrix}
\]

The equilibrium equation groups are

\[
f_1 = f_3 = 0, \ f_2 = y_1 - y_2, \ f_4 = y_2
\]
In matrix terms, the equilibrium matrix is
\[
\begin{bmatrix}
0 & 0 \\
1 & -1 \\
0 & 0 \\
0 & 1
\end{bmatrix}
\]
Equations (18), (19) and (21) bring
\[
S = A^T KA
\]
\[
= \begin{bmatrix}
0 & 0 & 0 \\
1 & -1 & 0 \\
0 & 0 & 0 \\
0 & 1 & 0
\end{bmatrix}
\begin{bmatrix}
k_1 \\
k_2 \\
k_3 \\
k_4
\end{bmatrix}
= \begin{bmatrix}
0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0
\end{bmatrix}
\]
\[
S = A^T KA
\]
\[
= \begin{bmatrix}
0 & -1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0
\end{bmatrix}
\]
By making an elementary row transformation on \( S \), the matrix is derived as
\[
S' = \begin{bmatrix}
k_2 & 0 & -k_2 & 0 & 0 & 0 \\
0 & k_1 + k_4 & 0 & 0 & 0 & -k_4 \\
-k_2 & 0 & k_2 & 0 & 0 & 0 \\
0 & 0 & 0 & k_3 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & -k_4 & 0 & 0 & 0 & k_4
\end{bmatrix}
\]
The rank of matrix \( S \) is 4, so the dimension of null space of matrix \( S \) is 2. The mobility of the mixed six-bar linkage is 2. Thus, the result is the same as (16).

IV. APPLICATIONS OF NEW THEORY ON SPECIAL KINEMATIC CHAINS

A. Mobility calculation of mechanisms with passive constraints

This method is applied to mechanisms with passive constraints appropriately, as it is no need to take them into consideration. That is to say, the mobility can be calculated directly without removing passive constraints.

Just like the kinematic chain in Fig. 4a, its method of transformation into network graph in Fig. 4b is similar to previous mechanisms.
After analyzing the network graph of mechanism in Fig. 4b, it brings

\[
S = A^T K A
\]

\[
\begin{bmatrix}
0 & -1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & -1 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
k_1 \\
k_2 \\
k_3
\end{bmatrix}
= \begin{bmatrix}
k_1 \\
k_2 \\
k_3
\end{bmatrix}
\]

\[
\begin{bmatrix}
0 & 1 & 0 & 0 & 0 \\
-1 & 0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & -1 & 0 & 1 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
k_2 \\
k_3
\end{bmatrix}
= \begin{bmatrix}
k_2 \\
k_3
\end{bmatrix}
\]

By making an elementary row transformation on \(S\), the matrix is

\[
S' = \begin{bmatrix}
k_2 & 0 & -k_2 & 0 & 0 \\
0 & k_1 & 0 & 0 & 0 \\
0 & 0 & -k_4 & 0 & k_4 \\
0 & 0 & 0 & k_3 & 0 \\
0 & 0 & 0 & 0 & k_5
\end{bmatrix}
\]

\[
\begin{bmatrix}
k_2 \\
k_3
\end{bmatrix}
= \begin{bmatrix}
k_2 \\
k_3
\end{bmatrix}
\]

The rank of matrix \(S\) is 5, so the dimension of null space of matrix \(S\) is 1. Chebyshev–Gruebler’s equation brings \(\text{DOF} = 1\). So the result is the same as (16).

B. Mobility calculation of mechanisms with common constraints

This method is also applied to mechanisms with common constraints, but its principles of transformation from kinematic graph to network graph of mechanism are partly different. The differences are:

- The nodes in network graph of mechanism denote the bodies;
- The elastic links denote the constraints between bodies or bodies and the root.

According to the principles, the transformation of the wedge mechanism in Fig. 5a is showed in Fig. 5b.

\[
\begin{bmatrix}
k_1 \\
k_3
\end{bmatrix}
= \begin{bmatrix}
k_1 \\
k_3
\end{bmatrix}
\]

Obviously, its network graph of mechanism has no different with that of the four-bar linkage in Fig. 1b. So the mobility of this wedge mechanism with common constraints is single.

C. Mobility calculation of mechanisms with higher pairs and passive degrees of freedom

For mechanisms with higher pairs and passive degrees of freedom, the passive degrees of freedom need to be removed just like Chebyshev–Gruebler’s method.

Fig. 6a shows a mechanism with higher pairs and passive degrees of freedom. After removing its passive degrees of freedom, its principles of transformation into network graph of mechanism (Fig. 6b) are similar to the mechanisms with common constraints.

\[
\begin{bmatrix}
k_2 \\
k_3
\end{bmatrix}
= \begin{bmatrix}
k_2 \\
k_3
\end{bmatrix}
\]

Obviously, the network graph of the mechanism in Fig. 6b is the same as the four-bar linkage in Fig. 1b after removing its passive degrees of freedom. Thus, we can get its mobility with no effort as its calculation is in previous section.

V. Conclusions

The above mentions approve that this new method applies to calculate the mobility of planar mechanisms simply. It is effective to analyze degrees-of-freedom of open kinematic chains, closed kinematic chains, mixed kinematic chains and some special kinematic chains with common constraints, passive constraints, etc. The crux of this method is the transformation from kinematic graph to network graph of mechanism which needs to be appropriate and correct. Besides, for some simple planar
mechanisms, their mobility can be counted by inspection and for some kinematic chains whose network graph of mechanisms are identical have the same number of mobility.
