Objective: Atosiban and ritodrine are frequently used tocolytics. Only a few studies investigated the hemodynamic effects of atosiban. We therefore aimed to study the effects on the blood pressure (BP) and BP-amplification.

Methods: Twenty healthy female volunteers (19-41 yrs) were given atosiban (300 µg/min over 2 h) and placebo intravenously (IV) in a random crossover design. Eight of them also received ritodrine IV in escalating doses up to 400µg/min over 2 h. The brachial artery (BA) blood pressures (BP) were taken by an oscillometric device (OMRON 705-IT) and the BP at the common carotid artery (CCA) and the radial artery (RA) were calculated using applanation tonometry. This was done at the steady state of the highest dose. Statistical analysis was done using Friedman and Wilcoxon test setting value of significance at 0.05.

Results: Effects on atosiban/placebo on N = 20 did not differ from N = 8.

| Parameters | Ritodrine (n = 8) | Atosiban (n = 8) | Placebo (n = 8) | p-value

CI (cardiac index); SV (stroke index); MAP (mean arterial pressure); TPR (total peripheral resistance index); HR (heart rate); AGPP (augmentation index at HR 75).

* Friedman-test; * significant vs. atosiban; # significant vs. placebo.

Conclusion: Ritodrine has important hemodynamical effects reflected by cardiac stimulation (increase in CI through HR increase) and a decrease in peripheral resistance (TPR) with a trend for decreasing wave reflections (AGPP). The effect of atosiban on central and peripheral hemodynamics did not differ from placebo.
