disease and have different effects on the lumen diameter (LD) of the carotid artery. We hypothesised that changes in flow and shear stress in the common carotid artery may contribute to these differences in remodelling.

**Methods:** 10 treatment naive hypertensive subjects were recruited into a double blind, placebo controlled, randomised 3-way cross-over study comparing the effects of 7 days treatment with amlodipine or lisinopril. Brachial and carotid blood pressure (BP), common carotid artery (CCA) flow rate, IMT and LD were measured at the end of each treatment period. Magnetic resonance imaging-based computational fluid dynamics was used to calculate time averaged wall shear stress (WSS) in the carotid artery bifurcation. There were significant reductions in brachial and carotid BP with both active treatments compared to placebo, but brachial and carotid BP did not differ significantly between the antihypertensive agents. CCA flow rate was significantly lower and distal vascular resistance was higher following lisinopril treatment compared with amlodipine. WSS on the inner wall of the CCA was significantly lower after lisinopril treatment compared with amlodipine.

**Conclusion:** Amlodipine causes increased carotid blood flow and increased WSS compared with lisinopril, probably as a result of greater cerebrovascular vasodilatation. These effects could account for differences in arterial remodelling caused by these agents.

**P4.05 NONINVASIVE PULSE WAVE ANALYSIS FOR MONITORING THE CAROTID WAVEFORM DURING LAPAROSCOPIC CHOLECYSTECTOMY**

**Aim of Study:** Due to absorption of carbon dioxide and elevated intraabdominal pressure, pneumoperitoneum during laparoscopic cholecystectomy has potentially harmful intraoperative cardiovascular effects. Our aim was to test the usefulness of a non-invasive method for detecting these hemodynamic parameters.

**Methods:** A total of 35 patients, with low anaesthesia risk (ASA 1 and 2) who underwent laparoscopic cholecystectomy were investigated using SphigmoCor arterial wave analyzing system. Conventional pneumoperitoneum was performed, insufflation using carbon dioxide to an intrabdominal pressure of 8-12 mmHg. We determined the estimated central arterial pressure, augmentation pressure index, augmentation index, ejection duration and subendocardial viability ratio throughout the surgery. These parameters were recorded after induction of anaesthesia and during the inflation period of surgery.

**Results:** A significant increase in mean arterial blood pressure (84.5 ± 22.1 vs. 94.0 ± 14.4 mmHg, p = 0.04), aortic pulse pressure (29.5 ± 9.2 vs. 32.7 ± 11.5 mmHg, p = 0.04), augmented pressure (5.9 ± 4.1 vs. 11.0 ± 6.9 mmHg, p < 0.001) and corrugated augmentation index (20.1 ± 13.3 vs. 22.8 ± 12.9, p < 0.001) were recorded after insufflating the abdomen. After deflating the abdomen the measured parameters tended toward normalization.

**Conclusions:** The derived parameters suggested an increased mechanical cardiac activity and a raised peripheral vascular resistance along with increases in left ventricular end-systolic wall stress. SphigmoCor arterial wave analysis successfully documented hemodynamic changes occurring during laparoscopic surgery. Our results from this non-invasive technique correspond to data reported previously, using invasive hemodynamic monitoring.

**P4.06 DIFFERENTIAL EFFECTS OF NEBIVOLOL AND ATENOLOL ON CAROTID ARTERIAL WAVE INTENSITY**

C. Park, J. Sever, A. W. Khr, C. L. Chang, S. Thom, A. D. Hughes, N. Poulter

**Background** The hemodynamic effects of the vasodilator β-blocker nebivolol may differ from those of a conventional agent. Wave intensity analysis can describe the energy transported by wavefronts in the arterial system in the direction of wave propagation. A non-invasive ultrasound-based technique [1] was used to compare the effects of nebivolol and atenolol on carotid arterial wave intensity in patients participating in a hypertension treatment study.

**Methods** 38 hypertensive patients (age 63 ± 11yrs, 21 female) took part in a double-blind randomised cross-over study. All received bendroflumethiazide 2.5 mg for 6 weeks in advance, and throughout the study. We compared effects of nebivolol 5 mg and atenolol 50 mg on the magnitude of the initial systolic forward compression wave (S), the protodiastolic forward decompression wave (D) (both generated by the heart), the reflected compression wave (C) and local wave speed.

**Results.** The S and D waves were significantly smaller with atenolol than with nebivolol treatment but waveform reflection and wave speed did not differ.

**Medians (25th, 75th percentiles), * Wilcoxon’s signed rank test**

**Conclusions:** In hypertensive patients nebivolol has a more favourable effect than atenolol on left ventricular wave generation without increasing wave reflection. 1. Niki K, et al., Heart Vessels 2002; 17:12-21.

**P4.07 INFLUENCE OF LONG-ACTING ISOSORBIDE-5-MONONITRATE ADMINISTRATION ON LARGE ARTERIAL STIFFNESS IN PATIENTS WITH ESSENTIAL HYPERTENSION**

Cardiology Research Center, Moscow, Russian Federation

**AIM of this study was to evaluate the clinical efficacy of long-acting nitrates, isosorbide-5-mononitrate (ISMN), in addition to ACE inhibitor on artery stiffness in patients with essential hypertension. MATERIALS AND METHODS.**

40 hypertensive patients (mean age 61.3 ± 7.4 years, 9 male, 31 female, mean SBP/DBP = 158±17, 9/17, 9.7 ± 9 mmHg) received moexipril in individual titrated doses (mean dose 11.7 ± 4.8 mg daily) for 3 months. 20 patients, which retained SBP > 140 and/or DBP > 90 mmHg, received additional ISMN (50 mg daily) for 4 weeks. Other patients formed the control
