Purpose: A decrease in aortic stiffness could theoretically occur after several years of treatment but reduction has never been unequivocally demonstrated in clinical practice. Association with changes in blood pressure remained unclear.

Methods: This longitudinal observational study was conducted in 97 patients (63 ± 1 yrs, 47 women) with treated essential hypertension attending the outpatient hypertension clinic at Pompidou Hospital. Aortic stiffness and carotid pulse pressure were determined through carotid-femoral PWV and applanation tonometry. The first measurement of PWV was performed when brachial SBP was lowered below 140 mmHg under treatment. 66 patients had 3 PWV measurements, and 31 patients had 2 measurements during an extended follow-up (5.3 ± 1.2 yrs).

Results: The reduction in PWV (from 14.2 ± 4.2 to 11.1 ± 2.4 m/s, linear mixed model, P = 0.0001) was associated with a reduction in central SBP (from 132 ± 2 to 122 ± 2 mmHg, P = 0.0001) and central PP (from 59 ± 2 to 54 ± 2, P = 0.001), whereas brachial SBP and PP did not significantly change. In multivariate analysis, the decrease in PWV was significantly associated with age (P = 0.005), duration of follow-up (P = 0.0011), presence of diabetes (P = 0.005) and reduction in brachial MBP (P = 0.005), independently of gender, changes in brachial PP, glomerular filtration rate and hypercholesterolemia.

Conclusion: These results indicate that a large decrease in aortic stiffness (>22%) can be observed in the long term when hypertensive patients were treated under conditions of routine clinical practice. This reduction of aortic stiffness was associated with a reduction in central SBP and PP contrasting with no change in brachial SBP and PP.

P4.05 NONINVASIVE PULSE WAVE ANALYSIS FOR MONITORING THE CARDIOVASCULAR EFFECTS OF PNEUMOPERITONEUM DURING LAPAROSCOPIC CHOLECYSTECTOMY

Aim of Study: Due to absorption of carbon dioxide and elevated intraabdominal pressure, pneumoperitoneum during laparoscopic cholecystectomy has potentially harmful intraoperative cardiovascular effects. Our aim was to test the usefulness of a non-invasive method for detecting these hemodynamic parameters.

Methods: A total of 35 patients, with low anæsthesia risk (ASA 1 and 2) who underwent laparoscopic cholecystectomy were investigated using SphigmoCor arterial wave analyzing system. Conventional pneumoperitoneum was performed, insufflation using carbon dioxide to an intrabdominal pressure of 8-12 mmHg. We determined the estimated central arterial pressure, augmentation pressure, augmentation index, ejection duration and subendocardial viability ratio throughout the surgery. These parameters were recorded after induction of anaesthesia and during the inflation period of surgery.

Results: A significant increase in mean arterial blood pressure (84.5 ± 22.1 vs. 94.0 ± 14.4 mmHg, p = 0.04), aortic pulse pressure (29.5 ± 9.2 vs. 32.7 ± 11.5 mmHg, p = 0.04), augmented pressure (5.9 ± 4.1 vs. 11.0 ± 6.9 mmHg, p < 0.001) and corrugated augmentation index (20.1 ± 13.3 vs. 22.8 ± 12.9, p < 0.001) were recorded after insufflating the abdomen. After deflating the abdomen the measured parameters tended toward normalization.

Conclusions: The derived parameters suggested an increased mechanical cardiac activity and a raised peripheral vascular resistance along with increases in left ventricular end-systolic wall stress. SphigmoCor arterial wave analysis successfully documented hemodynamic changes occurring during laparoscopic surgery. Our results from this non-invasive technique correspond to data reported previously, using invasive hemodynamic monitoring.

P4.06 DIFFERENTIAL EFFECTS OF NEBIVOLOL AND ATENOLOL ON CAROTID ARTERIAL WAVE INTENSITY

C. Park, J. Sever, A. W. Khir, C. L. Chang, S. Thom, A. D. Hughes, N. Poulter

Background The hemodynamic effects of the vasodilator β-blocker nebivolol may differ from those of a conventional agent. Wave intensity analysis can describe the energy transported by wavefronts in the arterial system in the direction of wave propagation. A non-invasive ultrasound-based technique [1] was used to compare the effects of nebivolol and atenolol on carotid arterial wave intensity in patients participating in a hypertension treatment study.

Methods 38 hypertensive patients (age 63 ± 11yrs, 21 female) took part in a double-blind randomised cross-over study. All received bendrofluamethizide 2.5 mg for 6 weeks in advance, and throughout the study. We compared effects of nebivolol 5 mg and atenolol 50 mg on the magnitude of the initial systolic forward compression wave (S), the protodiastolic forward decompression wave (D) (both generated by the heart), the reflected compression wave (C) and local wave speed.

Results. The S and D waves were significantly smaller with atenolol than with nebivolol treatment but wave reflection and wave speed did not differ.

Conclusions: In hypertensive patients nebivolol has a more favourable effect than atenolol on left ventricular wave generation without increasing wave reflection. 1. Niki K, et al., Heart Vessels 2002; 17:12-21.

P4.07 INFLUENCE OF LONG-ACTING ISOSORBIDE-5-MONONITRATE ADMINISTRATION ON LARGE ARTERIAL STIFFNESS IN PATIENTS WITH ESSENTIAL HYPERTENSION

Cardiology Research Center, Moscow, Russian Federation

AIM of this study was to evaluate the clinical efficacy of long-acting nitrates, isosorbide-5-mononitrate (ISMN), in addition to ACE inhibitor on artery stiffness in patients with essential hypertension. MATERIALS AND METHODS. 40 hypertensive patients (mean age 61.3 ± 7.4 years, 9 male, 31 female, mean SBP/DBP = 158.1 ± 17.9/91.7 ± 9.9 mmHg) received moexipril in individual titrated doses (mean dose 11.7 ± 4.8 mg daily) for 3 months. 20 patients, which retained SBP > 140 and/or DBP > 90 mmHg, received additional ISMN (50 mg daily) for 4 weeks. Other patients formed the control
