evaluate arterial wall parameters — IMT, distensibility and stiffness of CCA and cardiovascular risk factors (systolic and diastolic blood pressure (BP), body mass index (BMI) and smoking) — in hypertensive adolescents (HA) and metabolically healthy adolescents (NA).

Methods: Arterial wall structural and functional parameters were measured using echo-tracking method (Art. Lab system). BP was measured using BP monitor (Schiller ARGUS VCM). Twenty nine HA (17-18 yr. old, systolic BP ≥140 mmHg, diastolic BP ≥90 mmHg) and fifty five NA were included.

Results: Hypertensive adolescents had significantly greater values of IMT (49±8.49 μm vs. 46 ± 65.2 μm), distensibility (767 ± 121.94 μm vs. 692 ± 149.01) and carotid stiffness (2.88 ± 0.8 vs.1.86 ± 0.76) (p<0.05) compared with normotensive adolescents. They also had significantly higher weight, height, BMI and systolic blood pressure (p<0.05). No significant differences were found between smokers and non-smokers.

Conclusions: Disturbance of arterial wall parameters can be found in adolescents. Hypertensive adolescents had significantly greater values of IMT, distensibility and stiffness of common carotid artery than normotensive adolescents. Short period of smoking had no significant impact on CCA parameters.

Aim: To evaluate parameters of local and systemic arterial stiffness in patients with arterial hypertension (AH) and moderately marked carotid atherosclerosis (CA) with/without diabetes.

Materials and methods: Seventy-one patients (53 female) with AH (Grade 1-2) and CA (stenosis 20-55%) were enrolled in the study. Patients with diabetes were included in Group 1 (n = 29), and patients without diabetes - in Group 2 (n=42). Mean age in two groups was 67.4±6.5 vs. 66.4±6.9 (p=0.9); stenosis intensity - 38.3±9.3% vs. 33.9±8.0% (p=0.03). Both groups were comparable in sex ratio, incidence of cardiovascular risk factors, duration of HA and diabetes. Local stiffness of carotid arteries was evaluated by means of eTRACKING technology (ALOKA a7). Arterial stiffness parameter “β-index”, elastic modulus (Ep), arterial compliance (AC) and local pulse wave velocity (PWVLoc) were measured. Systemic arterial stiffness (pulse wave velocity, PWV) was evaluated using applanation tonometry (SphygmoCor).

Results: eTRACKING results for distal segment of the left common carotid artery (CCA) in Groups 1 and 2 were respectively: β-index 11.3±4.5 vs. 9.5±2.7 (p=0.03); 157.2±71.3 vs. 137.9±40.8 (p=0.0007). Local stiffness parameters for the distal segment of the right CCA in groups were respectively: β-index 10.3±3.8 vs. 8.8±2.9 (p=0.1); Ep 158.6±61 vs. 153.3±39.9 (p=0.09). There were no significant differences of AC and PWVLoc values between groups (p=0.05). PWV in Group 1 was significantly higher than in Group 2 (15.3±3.0 vs 13.0±2.8, p=0.0005).

Conclusions: Local and systemic arterial stiffness parameters in patients with AH and moderately marked carotid atherosclerosis were significantly higher in cases of diabetes than in its absence.

Background: The clinical benefit of chronic total occlusions (CTO) recanalisation is still being discussed. The aim of our study is to analyse long-term clinical results of CTO recanalisation drug-eluting stent implantation.

Methods: Patients were divided into groups: main group(A) consisted of patients with successful recanalization(n=321, mean age 58±9 years) compared with patients(control group B), who received medical therapy(n=264, mean age 61±10 years). The average follow-up was 1095±36 days.

Predictors of survival without coronary events (angina/myocardial infarction-coronary death) and chronic heart failure reoccurrence were analyzed employing Cox proportional hazards model.

Results: The frequency of angina and chronic heart failure reoccurrence was lower in the group with successful recanalization of CTO (p<0.05). According to the functional tests, after a period of 3 years of follow-up, the frequency of positive exercise tolerance tests was higher in group B(p<0.05). Patients in group A required less antianginal therapy (p<0.05).

Conclusion: Revascularization of CTO of coronary arteries is effective and feasible. Endovascular recanalization of CTO with drug-eluting stent implantation can improve the long-term prognosis.
with history of cardiovascular events had higher: number of swollen and tender joints, disease activity score (DAS28), body mass index (BMI), level of ESR, CRP, total cholesterol, triglyceride, augmentation index, aortic pulse pressure. Cases with cardiovascular event were also more likely to have taken higher doses of corticosteroids compared to controls. In statistical analysis, only triglyceride level and aortic pulse pressure were significant risk factor for the development of cardiovascular events (p<0.05). The other mentioned factors have drawn near but haven’t crossed the level of statistical significance.

Our aim was to study the influence of autonomic nervous system and other factors on arterial stiffness in young individuals at low cardiovascular risk. The study involved 136 healthy individuals (mean age 23.5 ± 6.7 years, 89 men and 47 women). The examination included: cardiovascular risk factors screening, heart rate variability (HRV), vascular stiffness, and endothelial function evaluation. Stiffness index was measured at baseline (SIbl) and after 500 mcg of sublingual nitroglycerin (SIng). Endothelial function was determined as the change of resistance index after inhalation of 400 mcg of salbutamol (EF). Vascular responses were calculated from digital pulse waves (DPW) registered using photoplethysmography. Vascular parameters did not differ between men and women. On multivariate analysis age and diastolic blood pressure were the only determinants of SIbl among the conventional risk factors (R² = 0.37, R² = 0.14, p<0.001). Age, systolic blood pressure, and EF were independent predictors of SIbl (R² = 0.97, R² = 0.33, p<0.001). Among HRV parameters added to the above models low parasympathetic activity and elevated sympathetic activity evaluated by pNN50 and low frequency waves spectrum (LF), respectively, were independent predictors of higher levels of SIbl (p<0.00001 for each parameter). The model explained nearly 40% of SIbl variability (R² = 0.62, R² = 0.38, p<0.00001). Only pNN50 was independently related to SIbl in multivariate model (p=0.01) marginally increasing its predictive value (R² = 0.64, R² = 0.41, p<0.00001). Thus, autonomic nervous system significantly affected baseline arterial stiffness evaluated by DPW analysis in young individuals. Whereas SIbl is minimally influenced only by parasympathetic tone and more precisely reflects cardiovascular risk factors effects on arterial wall.

Context and objective: It is known that patients, with a diagnosis of metabolic syndrome (MetS) having three or more cardiometabolic risk factors (CmRF) are associated with an increased cardiovascular risk. The study aimed at evaluating the increase of the risk depending on a number of individual CmRF while evaluating early subclinical atherosclerosis indicators measuring arterial markers, such as PWV and Aix, as well as eGFR.

Results: A total of 530 patients with at least two CmRF according to the NCEP ATP III metabolic syndrome definition were screened for the assessment of subclinical atherosclerosis (measuring PWVradial, PWVfemoral, Aix@HR75), as well as eGFR (using the MDRD formula). A correlation between Aix@HR75 and eGFR (Pearson Correlation Coef. 0.435, p<0.001) was found. Between the two groups with two, three or four CmRF, increasing PWVradial (ANOVA, p=0.032) (Figure 1), decreasing Aix@HR75 (p<0.01) and deteriorating eGFR (p<0.01) (Figure 2) with an increasing number of CmRF were noted. The difference in PWVfemoral between the groups was not statistically significant.

Conclusion: For CVD risk prediction, every individual trait and a number of traits of CmRF must be considered. While Aix increases, eGFR decreases with an increasing number of CmRF. Affecte arterial markers were detected in patients with just two CmRF and further worsening was observed with each additional factor, suggesting that individual CmRF is important when defining the CVD risk for patients with or without MetS.

Background: Arterial stiffness represents a strong predictor of the cardiovascular events and mortality, but seems to be influenced by eNOS mutations (responsible for alteration of NO release).

Purpose: to investigate the relationship between T786C mutation and arterial rigidity. Material and method 70 patients were investigated (63.4% females), mean age 59.81±11.01 years, without significant differences between genders. Genetic polymorphism of T786C (using PCR method), and arterial rigidity (using a TensioMed®Arteriograph) were determined.

Results: The distribution according to the presence of genotypes was: 49.3% were negative (TT), 33.8% heterozygous (CT) and 16.9% homozygous (CC). Globally, there was significant difference of the PWVao values between homozygous and heterozygous or negative patients: 11.65±1.87m/sec in CT patients vs 9.75±1.75m/sec in TT patients (p=0.005). Even though statistical significance was not reached for the rest of the parameters, an ascending trend can still be noticed, CC (in comparison with CT, respectively TT) patients showing higher levels of PWVao (42.71±15.24% vs 37.97±17.24% vs 34.46±18.11%, p=NS), Aixb (15.66±31.33% vs 13.1±26.85% vs 2.07±31.96%, p=NS). In the same time, the relationship was also present in women (for PWVao, CC genotype women
