Although traditional risk factors may account for 90% of the attributable cardiovascular risk their prediction of CVE is weak based on SCORE Chart. We need to find new established risk factors and to detect subclinical cardiovascular disease to predict future coronary events. Stiffening of the aorta is one of the earliest surrogate marker of vascular damage and measurement of arterial stiffness has a growing interest in risk assessment. Aim: Authors investigated the correlation between the high risk state characterized by SCORE (>5%) and elevated aortic pulse wave velocity (PWVao, increased arterial stiffness) measured by arteriograph.

Subject and Methods: 2243 adults were included to the analysis in which SCORE could be calculated. Sensitivity, specificity and predictive values of SCORE in detecting increased PWVao were calculated by SPSS software.

Results: Elevated PWVao (>9,62 m/s) was detected in 38% of patient population but sensitivity of SCORE high risk category (>5%) to detect elevated PWVao was poor (33%) despite high specificity (88%) while false negative cases were in 26%. Sensitivity of SCORE was a little bit better in males (65%) but much poorer in females (17%). 10% of males and 36% of females are underestimated by SCORE assessment. The ROC curve of SCORE at the cut-off value of 5% has shown 33% sensitivity but 89% specificity.

Conclusions: If PWVao is a good surrogate of preclinical atherosclerosis SCORE risk assessment seems to be quiet acceptable in men but not in women because it markedly underestimates females CV risk.

P1.42
PRECLINICAL ATHEROSCLEROTIC DISEASE: IS IT A MARKER OF RISK OF CARDIOVASCULAR EVENTS?

P. Forcada 1, C. Kotlier 1, O. Montana 2, C. Schulte 2, G. Millet 1, J. Guerrieri 1, D. Turri 1
1 Hospital Universitario Austral, Pilar, Buenos Aires, Argentina
2 Clinica Dim, Buenos Aires, Argentina

Aim: We compared the severity of vascular disease (VD) by ultrasonography in patients (p.) with and without cardiovascular events (CVE), to detect high risk asymptomatic individuals.

Methods: We did in the same procedure 1) CMT 2) Plaques characterization, 3) PWV and 4) FMD with a strict quality control. We set a score (VS) from 0 to 5 according to the severity of the VD. The CV Risk using Framingham score (FS) was also obtained from medical records.

Results: We performed a cross sectional, observational study on 581 p. (75% with CVE, 40% with stage I-II HT (ESH 07)) 53,2% males and 56% non CVE controls (52 ± 14 y.o. p. 001, 64% males p NS), FS was high (≥20%) for 216p. (30,8%), moderate (10-20%) for 204p. (30,8%), and low (<10%) for 261p. (40,2%).

Conclusions: 1- The higher the FS, the more the severity of the VD increases. 2- Although, we have found 54,2% with a low FS with moderate to severe VD and 18% of pts. with severe VD classified as low to moderate clinical risk.

P1.43
FRAMEINGHAM SCORE UNDERDIAGNOSES VASCULAR DISEASE IN PATIENTS UNDER CARDIOVASCULAR PREVENTION

P. Forcada 1, C. Kotlier 1, O. Montana 2, C. Schulte 2, G. Millet 1, J. Guerrieri 1, D. Turri 1
1 Hospital Universitario Austral, Pilar, Buenos Aires, Argentina
2 Clinica Dim, Buenos Aires, Argentina

Aim: Framingham score (FS) is used in clinical practice to estimate the CV risk of complications and is used as reference to evaluate new markers of CV risk. Recently ESH/ESC 07 guidelines stressed on the evaluation of subclinical vascular disease (VD). We analyzed, using an integrative ultrasound evaluation, the severity of VD according to increasing FS levels of risk.

Methods: We did in the same procedure 1) CMT 2) Plaques characterization, 3) PWV and 4) FMD with a strict quality control. We set a score (VS) from 0 to 5 according to the severity of the VD. The FS was obtained from medical records.

Results: We performed a cross sectional, observational study on 702 p. (54 ± 13y.o., 848 (64%) males). FS was high (≥20%) for 216p. (30,8%), moderate(10-20%) for 204p. (29%), and low (<10%) for 282p. (40,2%).

Conclusions: 1- The higher the FS, the more the severity of the VD increases. 2- Although, we have found 54,2% with a low FS with moderate to severe VD and 18% of pts. with severe VD classified as low to moderate clinical risk.

EARLY DETECTION OF ATHEROSCLEROTIC DISEASE IN MILD HYPERTENSIVE PATIENTS: A STRONG REASON TO REEVALUATE CARDIOVASCULAR RISK

P. Forcada 1, C. Kotlier 1, O. Montana 2, C. Schulte 2, G. Millet 1, S. Obregon 1, J. Guerrieri 1, D. Turri 1
1 Hospital Universitario Austral, Pilar, Buenos Aires, Argentina
2 Clinica Dim, Buenos Aires, Argentina

Aim: To analyze the incidence and severity of subclinical vascular disease (VD) using ultrasonography in patients (p.) with essential hypertension (HT). Methods: We did in the same procedure 1) CMT 2) Plaques characterization, 3) PWV and 4) FMD with a strict quality control. We set a score (VS) from 0 to 5 according to the severity of the VD. The CV Risk using Framingham score (FS) was also obtained from medical records.

Results: We did a cross sectional, observational study on 604 p. (479 with stage I-II HT (ESH 07) 53,2 ± 13 y.o., 63% males and 125 normotensive NT controls 51,7 ± 14 y.o. p.003, 62% males p NS)

Conclusions: 1- The severity of the VD is higher in patients with CVE even when the cut off points of normality may need to be adjusted. 2- The presence of a combination of vascular structural and functional disarrangements in asymptomatic subjects may suggest an increased risk of CVE. 3-A score of severity of VD
Conclusions: 1- Subclinical vascular disease is more frequent and severe in HT patients. 2- Indicators of subclinical vascular disease in this subset of p. allow a more precise diagnosis of subclinical vascular. (ESC/ESH guidelines 2007) 3- Vascular score of severity is higher in HT p. than in NT.

P1.45 GAMMA-GlutamylTransferase - Another Marker of the Cardiovascular Risk and Early Arterial Damage?
M. Kovaitė, L. Rylikštytė, Z. Petrušioniene, J. Badariene, V. Dzenkevičiute, A. Cypiene, A. Laucevičius. Centre of Cardiology and Angiology Vilnius University Hospital Santariskių Klinikos, Vilnius, Lithuania

Purpose: The aim of the study was to evaluate whether gamma-glutamyltransferase (γ-GT) is the marker of the cardiovascular (CV) risk assessed by the SCORE system and early arterial damage.

Methods. Serum levels of γ-GT, lipid profile, inflammatory markers and plasma glucose of 209 subjects (40-65 years old, 97 males) without clinically overt cardiovascular disease were checked. CV risk was evaluated by SCORE system. Parameters of arterial stiffness — aortic augmentation index (AIX/HR) and carotid-radial pulse wave velocity (PWV) - were obtained by application tonometry. Endothelium-dependent flow-mediated dilatation (FMD) in the radial artery and carotid IMT were assessed using high resolution B-mode ultrasonography.

Results: We found that SCORE system is associated with the γ-GT. SCORE risk significantly increased with each quartile of γ-GT (ANOVA, p < 0.003). γ-GT was significantly higher in high (≥ 5%) vs. low (< 5%) CV risk groups (43.82 vs 48.31 vs. 24.55 vs 22.66, p < 0.0001). In the univariate analysis γ-GT was significantly associated with the FMD in the brachial artery (r = 0.025), carotid-radial PWV (r = 0.042) and the presence of the carotid plaques (CP) (p < 0.002). The multiple regression analysis revealed that only gender (β = -0.28, p < 0.001), age (β = 0.301, p < 0.001) and triglycerides (β = -0.147, p = 0.046) were associated with FMD. PWV was independently associated with gender (β = -0.319, p < 0.001), glucose (β = 0.248, p < 0.001) and age (β = 0.218, p < 0.003).

Conclusions: The study suggests that serum γ-GT is a surrogate marker of CV risk. Elevation of γ-GT is associated with the increased endothelial dysfunction, arterial stiffness and carotid plaques, but not in the independent manner.

P1.46 Intima-Media Thickness Variation as Predictor of Atherosclerosis
I. M. Graf 1, F. H. B. M. Schreuder 2, J. M. Hameleers 1, W. H. M. Hess 1, R. S. Reneman 2, A. P. G. Hoeks 1
1 Mastricht University, Maastricht, Netherlands
2 University Maastricht Medical Centre, Maastricht, Netherlands

Background: The aim of the present study was to ascertain in vascular diseased patients the morphological characteristics of the common carotid artery (CCA), i.e. intima-media thickness (IMT) and IMT ipsi- and bilateral intra-subject variation (DIMT) and to relate them to the carotid bulb stenosis degree score to establish the relevance of each parameter.

Methods: In 154 patients, referred to the vascular laboratory for CCA examination (mean 66 years, 48% male), the carotid bulb was visualized in Doppler-mode to rate the stenosis degree based on blood flow velocities. CCA IMT and 2-DIMT were measured using multiple M-mode images (covering 3 heart beats). The association of morphological characteristics with stenosis degree was evaluated with Pearson correlation (r).

Results: Ipsilateral and bilateral 2-DIMT were stronger associated to stenosis degree score (r = 0.67 and r = 0.60, respectively, with p < 0.001) than IMT (r = 0.40, p < 0.001). The averaged IMT increased slightly for stenosis degree 5 and abruptly for the two highest values (r = 0.93, p = 0.001). Mean ipsi- and bilateral 2-DIMT presented a consistent graded increase with stenosis degree over the entire range (0-7), reaching a correlation close to 1 (r = 0.98 and r = 0.97, respectively, p < 0.001).

Discussion: Although CCA is a region less prone to plaques, the morphological characteristics of CCA are positively correlated with stenosis degree score. The present study indicates that ipsi- and bilateral 2-DIMT exhibit a stronger relation than IMT to the severity of carotid artery stenosis, underlining that 2-DIMT carries different information than IMT. In conclusion, in the CCA, 2-DIMT rather than IMT substantiates patient risk evaluation.

P1.47 Correlation Between Indicators of Arterial Stiffness and Estimates of Cardiovascular Events: Promoting Cardiovascular Risk Stratification in Clinical Practice
E. Malisi, C. Morelli, F. Santini, M. Kozaková, C. Palombo. Department of Internal Medicine, University of Pisa, Pisa, Italy

Background: Aortic and carotid stiffness are independent predictors of all cause, cardiovascular, and cerebrovascular morbidity and mortality in several clinical conditions as well as in the general population.

Aim of the study: was to investigate the associations between non-invasively determined aortic and carotid artery stiffness with estimates of absolute cardiovascular (CV) risk in healthy subjects and subjects with risk factors.

Materials: 139 subjects were recruited [104 with one or more CV risk factors (cases: 46 males, mean age 49 years), 35 healthy controls (16 males, mean age 43 years)]. Common carotid artery stiffness was investigated by an ultrasound system with wall track option (Aloka SSD-5500, Tokyo), providing a single point local wave speed (WS). Aortic stiffness was estimated by the carotid-femoral pulse wave velocity (CF-PWV) (Compil, Paris). Ten-year absolute CV risk was estimated using both the Framingham risk score (FRS) chart and the Edinburgh University Risk Chart (EÜR), including echocardiographic left ventricular hypertrophy.

Results: Cases had significantly (p < 0.001) higher CF-PWV (10.5 ± 2.2 vs 8.6 ± 1.3 m/s), WS (7.6 ± 1.4 vs 5.8 ± 0.8 m/s), FRS (10.8 ± 6.2 vs 3.1 ± 3.1%), and EURC score (21.5 ± 16 vs 6.5%). Significant positive correlations (p < 0.001) were observed for CF-PWV and WS with FRS (r = 0.56 and 0.52, respectively) and EURC score (r = 0.64 and 0.61, respectively). When subcdiving CF-PWV and WS in tertiles a significant intertertile difference was observed only for progressively increasing values of EURC score.

Conclusions: indices of subclinical cardiovascular involvement obtained by an integrated ultrasonographic investigation may help to promote CV risk stratification in clinical practice.

P1.48 Aortic Dissections: Why a Patient Has to Wait (Moscow-Based Retrospective Study)
O. Potlikina, V. Vikentyev. Moscow State University of Medicine and Dentistry, Moscow, Russian Federation

Aortic dissections (AD) are considered among most serious life-threatening conditions requiring emergency medical intervention. However, delays in recognition and treatment often occurred.

Our aim was to determine mean time intervals between 1) fist symptoms appearance (diagnostic delay, DD), 2) fist contact with a doctor (Doctor-related delay, DRD) and final establishing of a confirmed diagnosis.

We analyzed 37 cases of patients admitted to general hospital with AD (84.6% males, mean age – 58.3 years).

Type A AD occurred in 38.9% cases, type B - in 41.1%. The most frequent risk factors were atherosclerosis and hypertension, 94.8%. We identified 1 case of Marfan syndrome and 1 case lues teriall. Thoracic pain was observed in all cases: 38% patients complained of back pain and 84.6% of anterior chest pain. Abnormal pulsation and murmurs were found in 33.3% and 25.6% of all cases: 38% patients complained of back pain and 84.6% of anterior chest pain. Abnormal pulsation and murmurs were found in 33.3% and 25.6% of all cases: 38%
