Objective: It is well known that smoking and obesity are cardiovascular risk factors. However, many smokers fear to stop, thinking that following increase in weight will counterbalance the positive effect of smoking cessation. Our aim was to analyze the effect of smoking and obesity on early arterial damage in hypertensive men.

Methods: Hypertensive men without cardiovascular disease were included into the study (n=88, age 48.8±4.1). All patients underwent detailed assessment of cardiovascular risk. Carotid ultrasound (Art Lab System V.2.0), measurements of arterial stiffness and aortic blood pressure by applanation tonometry (Sphygmocor v.7.01) and sphygmomanometry (Vasera VS-1000) were performed in order to evaluate early arterial damage.

Results: Smokers (n=30) were younger as compared to non-smokers (n=58) – 48.5±3.91 vs. 49.28±5.0 years, p<0.05. Non-smokers had higher body mass index (31.5±3.6 vs 29.6±4.0, p<0.05), heart rate (69.1±10.2 vs. 60.7±11.0, p<0.05), and aortic mean blood pressure (101.4±14.5 vs. 108±12.11), but no aortic pulse pressure (37.9±7.4 vs. 37.3±10.7, ns). However, the aortic augmentation index AIx(AR) (22.5±9.75 vs. 15.6±8.9, p<0.001), heart-ankle stiffness index adjusted for blood pressure (CAVI-right 7.9±0.9 vs. 7.3±1.3, CAVI-left 7.8±0.9 vs. 7.2±1.2, p<0.01) and intima media thickness (0.65±0.17 mm vs. 0.56±0.13 mm, p<0.05) were significantly higher in smokers as compared to non-smokers. Smokers also had higher prevalence of the carotid plaques (p<0.05). Carotid-radial and carotid-femoral pulse wave velocity (Sphygmocor) didn’t differ significantly (respectively, 9.2±1.5 vs. 9.25±1.1 m/s; 8.6±1.6 vs. 8.54±1.3 m/s, ns).

Conclusion: Although non-smoking hypertensive patients tend to be older and more obese, the smokers have worse arterial parameters in our study group.

INCREASED PULSE PRESSURE IS ASSOCIATED WITH LONG LEFT VENTRICULAR EJECTION DURATION IN ISOLATED SYSTOLIC HYPERTENSIVES

K.D. Reesink, E. Hermeling, J. Waltenberger, A.P.G. Hoekx

Cardiovascular Research Institute Maastricht, Maastricht, Netherlands

Background: Apart from stiff arteries, increased pulse pressure is associated with increased left ventricular (LV) contractility. We investigated whether elevated LV performance can be derived from carotid artery diameter waveforms in hypertensives.

Methods: We obtained common carotid artery (CCA) diameter waveforms by ultrasound in 8 isolated systolic hypertension (ISH) patients (sys/dia: 154±17/77±13 mmHg, age 70±18 yrs). By dedicated signal processing we obtained, with good precision (<10%), left ventricular isovolumic contraction (ICT) and ejection durations (ET) from the diameter curve, as well as diastolic diameter (Dd), distension (D), relative distension (D/Dd), and distensibility (DC) and compliance coefficients (CC).

Results: Dd was 7.9±1.0 mm, ΔD was 0.30±0.12 mm, ΔD/Δd thus 4.2±2; pulse pressure was 77±16 mmHg. DC was 10.5±5.3 mPa and CC was 5.5±0.2 mPa/mm² ΔP, clearly linking the elevated pulse pressure to reduced arterial stiffness. Heart rate was 76±18 min⁻¹ while LV ICT and ET were 40±7 ms and 31±46 ms, respectively. LV dp/dtmax, estimated from the diastolic blood pressure-to-ICT ratio, was 1991±566 mmHg/s, suggesting no conspicuous contribution of LV contractility to increased pulse pressure in ISH. Within the group, however, there was a large spread in LV performance primarily related to ET and heart rate. Interestingly, ET showed a strong correlation with pulse pressure (r²=0.85, p<0.01), suggesting long ejection duration contributes to high pulse pressure in some patients.

Conclusion: Increased left ventricular performance, as reflected by ejection duration, can be observed and discriminated in isolated systolic hypertensives by diameter waveform analysis.

EVALUATION OF CENTRAL BLOOD PRESSURE AND AUGMENTATION INDEX IN PATIENTS WITH ISOLATED AMBULATORY AND ISOLATED OFFICE HYPERTENSION: THE VOBARNO STUDY

University of Brescia, Brescia, Italy

Different BP patterns have been identified by the use of office and 24 hours BP measurement: sustained normotension(NT),isolated office hypertension(INO),isolated ambulatory hypertension(IAH)and hypertension (HT).Pulse wave analysis has been proposed for evaluation of central BP:“augmentation index”(AIx)is an accepted indirect index of arterial stiffness.Aim of our study was to assess the relationships between PWA and BP patterns in a general population in Northern Italy.Methods In 242 untreated subjects( age 54±9 yrs,BMI 25±4, 47 males)radial artery applanation tonometry and PWA were used to derive central aortic pressures and AIx.All subjects underwent laboratory examinations and clinic and 24 h BP measurement.-Subjects were divided into subgroups:NT(office BP<140/90 and 24h BP<125/80 mmHg),IHO(office BP<140/90 and 24h BP<125/80 mmHg),IAH(office BP<140/90 and 24h BP<140/90 and 24h BP<125/80 mmHg)and HT(office BP>140/90 and 24h BP>125/80 mmHg).

Results: Patients with IAH and HT were older than NT(59±5.8 and 55±4.3 vs 51±1.64 yrs p<0.01),BMI was higher in IHO and HT than in NT(25.5±3.9 and 26.8±4.3 vs 23.7±3.3, p<0.01).After adjusting for confounding variables(including also mean BP and HR)AIx was significantly higher in IHO,IAH and HT in comparison to NT(31.1±1.0, 30.8±1.8, 31.3±1.0 vs 26.6±1.0,p<0.01).Central SBP was significantly higher in HT, but in IHO and IAH, than in NT(120±3.0, 120±0.6, IAH 121±0.1±1.2 vs NT 117±0.7 mmHg,p<0.01).Conclusion:In a general population sample central SBP and AIx are greater in patients with sustained, office or ambulatory hypertension.In IAH,despite normal brachial BP,central BP is significantly increased, possibly contributing to increase cardiovascular risk.

RELATION BETWEEN PULSE WAVE VELOCITY AND PREDICTORS OF CLINICAL OUTCOME IN ARTERIAL HYPERTENSION

V. Aursulesei 1, G. Datcu1, M.D. Datcu1.

1 University of Medicine and Pharmacy, Iasi, Romania, ''Sf. Spiridon'' University Hospital, 1st Medical Cardiology Department, Iasi, Romania

Objective: to evaluate the relation between pulse wave velocity (PWV), an independent marker of cardiovascular risk and other parameters with prognostic significance: intima media thickness (IMT), left ventricular hypertrophy (LVH) and flow mediated vasodilation (FMD) in patients with essential arterial hypertension.

Material and Methods: 142 hypertensive patients (aged 50-75 years, 65% females, without diabetes) were studied before and after 6, 12 months of treatment with ACEI/channel blockers + Indapamide. PWV was assessed using Compilor method, IMT and FMD using carotidian/brachial ultrasound respectively. LVH was defined by index of mass (LVMi) and geometric patterns.

Results: 1. PWV is strongly related with LVMi and concentric hypertrophy irrespective the gender, moment of evaluation or regimen of treatment (p<0.05). Correlation with eccentric hypertrophy is evident at baseline only for females (r-test). 2. PWV is related with carotidian IAT (r=0.38, p=0.01) at baseline; after 12 months the relation remains only in ACEI subgroup (r=0.42, p=0.03). 3. Correlation with FMD exists only after adjusting for cardiovascular risk factors (ANCova).

Conclusion: our results suggest the complexe interrelation between non-invasive parameters of atherosclerosis, which is influenced by cardiovascular risk profile and antihypertensive regimen. The combination of these measurements is of stronger clinical relevance.

CAROTID PATHOLOGY AND RISK FACTORS IN HYPERTENSIVE PATIENTS FOR CEREBROVASCULAR DISEASE - CORRELATIVE CLINICAL, NEUROSONOGRAPHIC AND ECHOCARDIOGRAPHIC STUDIES

1 Katholikien University, Leuven, Belgium

Objective: to identify the clinical, neurosonographic and echocardiographic predictors of carotid pathology in hypertensive patients for cerebrovascular disease (CVD). A previous study has demonstrated a strong association between carotid pathology and CVD in the general population, indicating the potential role of carotid intima media thickness (IMT) as a predictor of CVD. However, the association between carotid intima media thickness and CVD in hypertensive patients has not been thoroughly investigated.
