Published online: 7 December 2019
Results: Compared to normal TT levels, TD patients (n=19) were older (59.6 ± 8.6 vs 52.0±10 years, P<0.05) with higher BMI (28.6 ± 4.0 kg/m² vs 27.0±4 kg/m², P<0.05). They had lower EF, SV and inversely, higher E/A' compared to controls. Similar results were obtained in the second stage. During the third stage, TD was also associated to a higher mitral E/E’ and PWVc-f. The association remained significant in multivariate analysis after adjustment for age and cardiovascular risk factors.

Conclusion: Testosterone deficiency associates to an unfavorable LV performance as well to central arterial stiffness, with an adverse outcome on cardiac energetic. This information adds clinical value on hormone lower level, in both cardiovascular risk assessment and stratification of future preventive strategies.

P7.12 CIRCULATING VASCULAR GROWTH FACTORS AND AORTIC INDICES IN GHANAIANS WITH DIABETES AND HYPERTENSION

Aim: To evaluate the progression over time of carotid and aortic stiffness and carotid remodeling in hypertensive patients, according to the presence of diabetes mellitus.

Methods: In this prospective observational study, 124 hypertensive patients (32 with Type 2 diabetes – HTDM, 40 without - HD, 52 with normal glucose tolerance – NGT) were evaluated at Visit 1 and after a 3.4±1.0-year follow-up (V1). Carotid-femoral pulse wave velocity (PWV), carotid intima-media thickness (cIMT), carotid stiffness (CS) and factors of angiogenesis as circulating vascular growth factors: vascular endothelial growth factor (VEGF), angioptiogen (Ang)1, Ang-2, which together with endogenous VEGF induces proliferation and the sprouting of new blood vessels, in Ghanaians with type 2 diabetes (TZDM) and hypertension (HTN).

Results: 72 DM plus HTN patients, 44 patients with T2DM only, 54 patients with HTN only and 39 subjects without T2DM nor HTN were included in the study. Aortic pulse wave velocity (PWVao) and aortic systolic pressure (SBPao), augmentation index (AIX) and aortic pressure pulse (PPao) were measured with TensioMed’s Arteriograph. Fasting blood samples were measured for blood glucose, lipid profile, Ang-1, Ang-2 & VEGF.

Conclusion: Vascular growth factors were related to arterial stiffness indices, Ang-2 independently, in Ghanaians, and higher in patients with both diabetes and hypertension than with either condition alone.
maladaptive remodeling, suggesting lower efficacy of conventional treatment on this vascular feature.

P8.3 AORTIC FLOW ALTERATIONS IN DILATED AND HYPERTROPHIC CARDIOMYOPATHY: NEW INSIGHT FROM QUANTITATIVE FLOW MRI

Aims: Aortic structural and hemodynamic alterations have deleterious effects on the left ventricle (LV). Our aims were to: 1) define indices of ascending aorta (AA) flow from MRI data and 2) assess changes in such indices in dilated (DCM) and hypertrophic (HCM) cardiomyopathies.

Methods: We studied 17 DCM (53±11years) and 15 HCM patients (56±16years) matched for age with 34 controls (53±10years). MRI AA through-plane velocities were automatically segmented to estimate flow curves throughout the cardiac cycle. Then, indices reflecting flow curve changes during the late systolic deceleration time interval (DT) were derived: a) T1/2: the time interval required for flow deceleration to reach half of its systolic peak, in percentage of DT, and b) DR 1/2: the decrease in flow during half of DT, in percentage of systolic peak.

Results: T1/2 was 56.3±6.6% and DR 1/2 was 43.5±6.5% in controls. AA flow waveform during late-systole changes significantly in cardiomyopathies. Indeed, while it tends to be steeper in HCM as reflected by significant (p<0.001) decrease in T1/2 (43.1±17.3%) and increase in DR 1/2 (54.9±16.1%), it tends to be flat in DCM as reflected by significant (p>0.001) increase in T1/2 (68.2±6.7%) and decrease in DR 1/2 (31.6±7.8%). Furthermore, such differences remained significant while accounting for gender, BMI and heart-rate (MANOVA).

Conclusion: We found significant changes in AA flow patterns in the presence of cardiomyopathies, reflecting changes in both LV contractile capacity and aortic cushioning. Such aortic indices might be of major usefulness in pathologies associating aortic stiffening with LV hypertrophy such as hypertension.

P8.4 NON-INVASIVE ASSESSMENT OF LOCAL PULSE WAVE VELOCITY USING ELECTROMECHANICAL SENSORS: FEASIBILITY STUDY IN A HEALTHY POPULATION

The assessment of local hemodynamics, namely in the carotid artery, has recently gained clinical relevance due to its significance in the development of coronary and cerebrovascular diseases. Local pulse wave velocity (PWV) constitutes one of the most important indices in carotid stiffness evaluation, but currently available devices require high technical expertise and specialized imaging technologies. This paper proposes two novel electromechanical double headed probes for non-invasive measurement of local PWV. The PWV is assessed in a single location and implies the determination of the time delay between the signals acquired simultaneously by either two acoustic or two piezoelectric sensors, namely placed 11 mm and 15 mm apart, at the carotid site.

The acoustic probe (AP) and the piezoelectric probe (PZP) were tested in 20 healthy volunteers aged 22.12 ± 1.96 years. Carotid PWV along with other time-based hemodynamic parameters were estimated. The values were also compared with carotid-femoral PWV measurements using a Complior device.

The mean local PWVs obtained were lower than those achieved in other studies, exhibiting values of 3.05 ± 0.96 ms-1 for the AP and 3.01 ± 0.77 ms-1 for the PZP. These results demonstrated that AP and PZP PWVs were linearly correlated, presenting a significant and strong relationship (R=0.76, p<0.001). Contrarily, these values were non-statistically significant with Complior PWV, presenting negative and very weak relationships (p>0.05).

Although studies will be extended to a more significant number of patients to differentiate between ages and healthy/non-healthy groups, these probes appear to be promising alternatives to local PWV stand-alone devices.

P8.5 EVALUATION OF VALVULOARTERIAL IMPEDANCE IN AORTIC VALVE STENOSIS BY USING CARDIAC MAGNETIC RESONANCE AND CAROTID ARTERY TONOMETRY

In aortic valve stenosis (AVS), valvulocentric impedance (Zva), as left ventricle (LV) afterload estimation, has been proposed in echocardiography (TTE) to predict adverse outcome better than conventional parameters such as aortic valve area (AVA). However its calculation method differs from standard temporal arterial characteristic impedance (Zc) assessment. The aim of our study was to apply the Zc concept of measurements to estimate Zva by using phase contrast magnetic resonance (PC-MR) and carotid tonometry.

Methods: 40 patients (76±13 years, 21 males) underwent MR with carotid tonometry and TTE.

- Zva-TTE was assessed with brachial systolic arterial pressure, TTE trans-valvar mean gradient and stroke volume index to body surface area.
- Zva-MR was assessed with pressure waveform from carotid tonometry, trans-valvar pressure gradient and Flow waveform on LV outflow track from PC-MR.

These methods were evaluated by comparing their links with diastolic dysfunction estimated by TTE E/Ea ratio.

Results: Zva values were higher in symptomatic patients using both TTE and MR. In univariate analysis, only Zva-MR was correlated with E/Ea (r=0.5, p=0.001).

In multivariate analysis of determinants of E/Ea, a significant model including age, Mean blood pressure, LV ejection fraction, LV mass and AVA was obtained (R²=0.41; p<0.01). When Zva-MR was included, the overall significance of the model was higher (R²=0.56; p<0.01). Only Zva-MR and LV Mass remained independently correlated to E/Ea.

Conclusions: By using MR in association with carotid tonometry, the calculation of Zva is feasible and can improve LV afterload assessment in AVS. This new way to estimate Zva may be clinically useful in patients evaluation.

P8.6 COMPARISON OF TRANSIT TIME ESTIMATION METHODS FOR THE DETERMINATION OF PULSE WAVE VELOCITY

Pulse wave velocity (PWV) has been shown to be a reliable marker for arterial stiffness. Its accuracy depends heavily on the estimation of the transit time (TT) between proximal and distal measured pulse waveforms. Several methods of determining the TT exist, but no consensus for the standardization of one of them has been reached yet. In this work, various state-of-the-art TT estimation methods and the resulting PWV values are examined.

In total, 118 pair-wise measurements using applanation tonometry on the carotid and femoral arteries from 59 patients over a wide age range (21-88 years), recorded by the SphygmoCor system, were examined. For the TT estimation, two traditional methods based on intersecting tangents (IT) and the maximum systolic upstroke (MSU) were used. Furthermore, the two recently proposed methods "diastole-patching" (DP), which compares the region in the foot of the proximal waveform, and the cross correlation of the complete waveform (CC) were compared.

The resulting PWVs differed significantly (p<0.05, Bonferroni corrected paired T-test) between the various methods, with exception of MSU vs. DP. The means ± standard deviations were 8.2±1.8m/s using IT, 7.6±1.9m/s for the MSU, 7.8±2.2m/s using DP, and 9.9±6.7m/s by calculation of the CC. Comparisons of single measurements lead to differences of even more than 6m/s.

Although the 2013 ESH/ESC Guidelines for the management of arterial hypertension suggest a threshold of 10m/s as an estimate of alterations of aortic function, no evaluation method is mentioned. Our results suggest that an agreement on the optimal TT estimation may be useful.
