in several population-based studies participating in the MARE (Metabolic syndrome and Arteries REsearch) Consortium the occurrence of specific clusters of Mets differed markedly across Europe and the US. The aim of the study was to investigate whether specific clusters of Mets are consistently associated with stiffer arteries in different populations. We studied 20,570 subjects from 9 cohorts representing 8 different European countries and the US participating in the MARE Consortium. Mets was defined in accordance with NCEP ATPIII criteria as the simultaneous alteration in ≥3 of the 5 components: abdominal obesity (W), high triglycerides (T), low HDL cholesterol (H), elevated blood pressure (B), and elevated fasting glucose (G). PWV measured in each cohort was “normalized” to account for different acquisition methods. Mets had an overall prevalence of 24.2% (4985 subjects). Mets accelerated the age-associated increase in PWV levels at any age, and similarly in men and women. Mets clusters TBW, GBW, and GTBW were consistently associated with significantly stiffer arteries to an extent similar or greater than observed in subjects with alteration in all the five Mets components even after controlling for age, sex, smoking, cholesterol levels, and diabetes mellitus in all the MARE cohorts. In conclusion, different component clusters of Mets showed varying associations with arterial stiffness (PWV).

P10.2 ARE INTERMEDIATE ANKLE-BRACHIAL INDEX VALUES IMPORTANT IN HYPERTENSION? INSIGHTS FROM A LARGE COHORT OF NEVER-TREATED HYPERTENSIVES

Objective: Ankle brachial index (ABI) is a diagnostic tool for peripheral arterial disease; moreover it has a prognostic value for future events. However, the role of intermediate ABI values (0.9 to 1.3) is still unclear. We investigated the interplay of intermediate ABI values with indices of subclinical organ damage in a large cohort of newly diagnosed, never treated hypertensives.

Design and Method: 1,127 newly diagnosed, never-treated hypertensives were recruited. ABI was measured with the oscillometric method and sub- jects with ABI <0.9 or >1.3 were not included. cfPWV, central BPs, Aix, left ventricular mass index (LVMI), CRP and eGFR were measured. The 10-year risk was calculated using the Framingham Risk Score.

Results: The cohort was young (age: 53 ± 12 years old), with mild-moderate hypertension (systolic BP: 151 ± 18 mmHg, diastolic BP: 90 ± 11 mmHg) and mean ABI value 1.15 ± 0.08. 57.7% were men, 41.3% smoked and 5.9% were diabetics. Left ventricular hypertrophy was detected in 42.2% and the 10-year CVD risk was 15.9 ± 9.6%. ABI correlated with cfPWV, central systolic BP, Aix, LVMI and CRP (r: -0.182, -0.268, -0.195, -0.075, -0.152 respectively, p<0.01 for all). The 10-year risk increased with lower ABI values (r=-0.077, p<0.01). After adjusting for confounders, patients with LVH had higher ABI levels; lower ABI values were observed with worsening eGFR (figure).

Conclusion: Intermediate ABI values carry prognostic information; they are related to large artery stiffness, impaired central hemodynamic indices, LVH, renal function impairment and 10-year risk of CVD. ABI measurements should be part of an integrated approach to hypertensive patients for both diagnostic and prognostic reasons.

P10.3 ARTERIAL STIFFNESS IS A BETTER PREDICTOR OF LEFT VENTRICULAR HYPERTROPHY THAN THE FRAMINGHAM RISK SCORE AND CENTRAL HEMODYNAMICS: INSIGHTS FROM 1,141 NEVER-TREATED HYPERTENSIVES

Objective: Left ventricular hypertrophy (LVH) heralds target organ damage and calls for aggressive therapeutic approaches. We investigated the predictive ability of arterial stiffness, central hemodynamic indices and the Framingham Risk Score (FRS) for detecting LVH.

Design and Method: 1,141 newly diagnosed, never-treated hypertensives were recruited. cfPWV, aortic BPs and Aix were measured. Left ventricular mass index (LVMI) was calculated according to the Devereux formula. LVH was defined as LVMI >95 g/m² (women) and >115 g/m² (men). The 10-year risk for CVD was calculated using the FRS.

Results: The cohort was young (age: 53 ± 12 years), with mild-moderate hypertension (BP: 151 ± 18/90 ± 11 mmHg). LVH was detected in 43% of patients and 10-year CVD risk was 16.1 ± 9.7%. LVMI had a stronger correlation with cfPWV (r: -0.39, p<0.001) compared to aortic SBP (r=-0.33, p=0.001), pulse pressure (r=0.306, p<0.001) and Aix (r=0.121, p=0.001). After adjusting for diabetes mellitus presence, eGFR, aortic SBP, cholesterol and 10-year CVD risk, cfPWV remained an independent predictor of LVMI (R²=0.243, B=1.60, p<0.001). In ROC analysis, cfPWV emerged as a better predictor of LVH (AUC: 0.735, p<0.001) compared to the FRS (AUC: 0.727, p<0.001), aortic SBP (AUC: 0.687, p<0.001), aortic pulse pressure (AUC: 0.705, p<0.001) and Aix: (AUC: 0.649, p<0.001).

Conclusion: In newly diagnosed, never-treated hypertensives, cfPWV is associated with LVMI and is a better predictor of LVH than the FRS, aortic BPs and Aix. High cfPWV values signify target organ damage, which extends beyond large artery stiffness and herald LVH. This has implications for risk stratification and choice of antihypertensive therapy.

P10.4 EARLY LIFE PREDICTORS OF BLOOD PRESSURE IN AFRO-CARIBBEAN YOUNG ADULTS: THE JAMAICA 1986 BIRTH COHORT STUDY
*The University of the West Indies (UWI), Kingston, Jamaica
*Kings College, London, UK
*University of Glasgow, Glasgow, Scotland, UK

Objective: In this study we examined the effects of birth weight (BWT) and early life socioeconomic circumstances (SEC) on systolic and diastolic blood pressure (SBP, DBP) among Jamaican young adults.

Study Design and Setting: Longitudinal study of 364 men and 430 women from the Jamaica 1986 Birth Cohort Study. Information on maternal SEC at birth and BWT were linked to information collected at 18-20 years old. Sex-specific multilevel linear regression models were used to examine whether adult SBP and DBP were associated with BWT and maternal SEC.

Results: In unadjusted models, SBP was inversely related to BWT z-score in both men and women (beta = -0.82 and -1.18, respectively) but achieved statistical significance only among women. After adjustments for current age, current BMI, current height, maternal age and mother’s occupation at child’s birth, a one standard deviation (SD) unit increase in BWT was associated with 1.16 mmHg reduction in SBP among women (95%CI: -2.15, -0.17; p = 0.021) and 1.34 mmHg reduction in SBP among women (95%CI: -2.21, -0.47; p = 0.003).

Conclusion: SBP at 18-20 years-old was lowest among those whose mothers had high SEC at birth than among those whose mothers were unemployed in early life.

P10.6 ARTERIAL WAVEFORM MEASURES IN THE VITAMIN D ASSESSMENT (VIDA) STUDY: RELATIONSHIPS WITH LIFESTYLE AND CARDIOVASCULAR FACTORS
*University of Auckland, Auckland, New Zealand
*University College London, London, UK
*Auckland University of Technology, Auckland, New Zealand
*Imperial College London, London, UK
*Austrian Institute of Technology, Vienna, Austria

Objectives: Identifying determinants of aortic waveform measures may help to define suitable strategies for improving arterial function. Our aim was to examine associations between lifestyle/cardiovascular risk factors variables and waveform measures as little is known about these.

Methods: Cross-sectional (baseline) analysis of 4830 adults aged 50-84 years participating in a vitamin D trial. Demographic and lifestyle variables were collected from questionnaires. Body mass index (BMI), cholesterol and brachial blood pressure (BP) were measured. Aortic systolic
