with Schelten's visual rating scale. Arterial wall parameters were measured by echo-tracking and applanation tonometry. RLS was assessed by contrast transcranial Doppler sonography with agitated saline. In order to explore the relationship between presence and load of DWMLs and possible risk factors logistic and linear regressions were applied.

**Results:** 29 (25.4%) migraineurs had DWMLs. They were significantly older (p<0.001), had more cardiovascular risk factors, thicker carotid intima-media (p=0.006), higher CS (p=0.004) and Alix (0.001) compared to migraineurs without DWMLs. The prevalence of large RLS was higher in patients with DWMLs, but not significant. The predictors of DWMLs were age (OR 1.11, p<0.001) and hypertension (OR 6.57, p<0.001). Higher DWMLs load was predicted by age, obesity, hypertension, and decreased HDL cholesterol. We established no relationship between presence and load of DWMLs and arterial wall parameters or RLS.

**Conclusions:** Age and traditional cardiovascular risk factors, but not arterial wall parameters, are predictors of DWMLs in patients with migraine.

**Objective:** To investigate, in a prospective cohort of individuals with type 1 diabetes: 1) the association between an aggregated z-score of low-grade inflammation markers (CRP, IL-6, sPLA2 and sICAM-1) and pulse pressure (PP), as a marker of arterial stiffness, and 2) the association of low-grade inflammation with incident fatal and non-fatal cardiovascular disease (CVD) and the potential mediating role of PP herein.

**Methods:** We prospectively followed 339 individuals with type 1 diabetes who were free of CVD at study entry and in whom brachial PP and markers of low-grade inflammation were measured at baseline. Data were analysed with linear and Cox-regression models, and all results presented are adjusted for age, sex, duration of diabetes, eGFR, UAE, MAP, BMI, total cholesterol, smoking, endothelial dysfunction and the use of antihypertensive medication.

**Results:** PP increased with 3.2 mmHg (95%CI: 0.4-6.0, p=0.025) per SD increase in the inflammation score. During the course of follow-up [median duration: 12.3 yrs (IQR: 7.6-12.5)], 85 individuals suffered a fatal (n=48) and/or non-fatal (n=53) CVD event. Low-grade inflammation was associated with higher incidence of CVD [HR = 1.56 (1.02-2.40), p = 0.042], as was PP (per 10 mmHg increase): HR = 1.27 (1.08-1.48), p = 0.007. Additional adjustment for PP attenuated the association between inflammation and incident CVD, but PP remained significantly associated with CVD (HR = 1.20 to HR = 1.45, p = 0.016).

**Conclusions:** Arterial stiffness, as expressed by PP, can partially explain the increased CVD associated with a low-grade inflammatory status in patients with type 1 diabetes. Treating inflammation may be a means to reduce the accelerated arterial stiffening that characterize these patients.

Arterial stiffness is an independent risk factor of cardiovascular events in the general population. While it is established that vascular stiffness is increased in patients with systemic lupus (SLE), studies investigating vascular stiffness in patients with antiphospholipid antibodies yielded conflicting results. In order to determine whether arterial stiffness was increased in patients with antiphospholipid antibodies we studied 53 patients with antiphospholipid antibodies and 109 controls matched for age and sex. Patients were 46.0±12.3 years-old, 40 female and 13 male. Twenty-six had primary antiphospholipid syndrome, 16 antiphospholipid syndrome associated with SLE. Clinical manifestations included arterial thromboembolic events n=14, venous thromboembolism n=28, obstetrical manifestations of APS n=9 and 11 patients were asymptomatic. Pulse wave velocity (PWV) was used to investigate arterial stiffness and was determined by applanation tonometry. PWV was increased in patients: 8.14±0.40 m/s and 7.24±0.20 m/s in controls (p=0.036). PWV was correlated with age (r=0.75; p<0.001) and systolic blood pressure (r=0.62; p<0.001). PWV was significantly increased in patients with arterial thrombosis than in controls (9.54±1.20 m/s and 7.23±0.20 m/s, respectively) or patients without arterial thrombosis (7.63±0.40 m/s;p=0.0416). PWV was not significantly different among various antiphospholipid profiles.

In summary patients with antiphospholipid syndrome have increased arterial stiffness, in particular patients with arterial thrombotic events. Arterial stiffness is significantly correlated with age and blood pressure but does not differ according to different antiphospholipid antibodies profiles.

**Objective:** It was suggested that, in the development of hypertensive microvascular remodeling, a relevant role may be played by laminin and fibronectin vascular content Aim of this study was to evaluate the amount of fibronectin and laminin within the tunica media of subcutaneous small arteries of normotensive subjects and essential hypertensive patients.

**Design and Methods:** We have investigated 6 normotensive control subjects and 10 essential hypertensive patients. All subjects were submitted to a biopsy of subcutaneous fat from the gluteal or the anterior abdominal region. Subcutaneous small resistance arteries were dissected and mounted on an isometric myograph, and the tunica media to internal lumen ratio was measured. In addition, the fibronectin and laminin content within the tunica media was evaluated by immunohistochemistry, with image analysis (% of area stained).
