Purpose: To determine the presence of vascular markers of premature atherosclerosis and metabolic correlates in a prospectively followed cohort of antiretroviral treated HIV-infected children.

Methods: Vascular assessment included: carotid intima-media thickness and brachial artery reactivity using vascular ultrasound; peripheral pulse wave velocity (PWV) using photoplethysmography; central PWV, arterial stiffness and impedance indices using an Echo-Doppler method; and only at follow-up, augmentation index and PWV by applanation tonometry. Disease markers, oral glucose tolerance, fasting lipid profiles and abdominal fat (single slice CT scan) were also determined.

Results: Twenty children were assessed at baseline (median age 12.6 [range 8.3-18.5] years; 50% female) and follow-up 21-25 months later. All were on combination antiretroviral therapy at baseline, but 5 were off therapy at follow-up with fewer receiving protease inhibitors. Resting systolic blood pressure and pulse pressure increased significantly over the study period (both p < 0.001), as did elastic modulus, stiffness index and input impedance (p = 0.0018, p = 0.0004, p = 0.0082, respectively). PWV measures by the different methods were not shown to correlate significantly. Dyslipidemia and abnormal glucose metabolism were present in 14 and 2 at baseline, and in 7 and 0 at follow-up, respectively. Visceral, subcutaneous and total abdominal fat content increased over time, but not significantly so.

Conclusions: An increase in measures of large arterial wall stiffness was observed over time. The reduction in dyslipidemia at follow-up may be related to fewer children receiving protease inhibitors. The potential risk of premature atherosclerosis in HIV-infected children on antiretroviral therapy warrants long-term monitoring of metabolic profiles and vascular function.

VASCULAR MARKERS OF PREMATUREATHEROSCLEROSIS IN PAEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS AND DISEASE, THERAPY, METABOLIC AND INFLAMMATORY CORRELATES

Purpose: Controversy exists as to whether the dyslipidemia and premature atherosclerosis which occurs in Systemic Lupus Erythematosus (SLE) is more due to disease activity or the therapy. We sought to determine the presence and correlates of vascular markers of premature atherosclerosis in paediatric SLE.

Methods: Vascular assessment included: carotid intima-media thickness and brachial artery reactivity using vascular ultrasound; peripheral pulse wave velocity (PWV) using photoplethysmography; central PWV, arterial stiffness and impedance indices using an Echo-Doppler method. These vascular indices were converted to z-scores from normal population data, and tested for normality with single sample T-tests. Augmentation index and PWV, using applanation tonometry, were only assessed in the latter half of the cohort. Disease activity scores, disease duration, cumulative prednisone dose, other medication use and fasting lipid, glycemic and inflammatory profiles were also determined and Pearson correlations performed.

Results: Seventy paediatric SLE were assessed (median age 15.7 [7.3-18.7] years and disease duration 1.4 [0.1-11.0] years, 80% females). The mean z-score adjusted data was significantly increased from normal for central PWV (+1.1, p < 0.001), input (+0.3, p = 0.04) and characteristic impedance (+0.8, p < 0.0001). Correlations were found between aortic elastic modulus and higher fasting glucose (R = 0.34, p < 0.007), and between stiffness index and homocysteine levels (R = 0.38, p < 0.008).

Conclusions: In treated paediatric SLE of relatively short duration, dyslipidemia, abnormal glycemic and inflammatory profiles were relatively common. Some stiffness measures were increased and others correlated with known atherosclerotic risk factors. These patients warrant long-term monitoring of vascular function and traditional and non-traditional risk factors.
