Published online: 7 December 2019
correlation coefficient between $r = 0.450$ (cfPWV and diastolic blood pressure) and $r = 0.128$ (between CAVI and triglycerides). After adjustment for age and sex the correlation remains the same with the cfPWV. However, it is only maintained with the CAVI only with blood pressure. Subjects with MetS have odds ratio (OR) for both cfPWV $> 10$ m/sec ($OR = 1.884$, 95% CI 0.996–3.486) and CAVI $> 9$ ($OR = 1.810, 95\%\ CI 0.749–4.372$).

Conclusions: The cfPWV showed the positive correlation, after adjusting it for age and sex with all the components of the MetS, however the CAVI showed the positive correlation with the arterial pressure.

Background: Markers of central haemodynamics have in recent years emerged as promising predictors of cardiovascular disease (CVD). Central haemodynamics are affected early in the development of vascular aging and affect organs directly attached to large arteries. Carotid-Femoral pulse wave velocity (c-f PWV), Augmentation index (Aix), and central systolic blood pressure (cSBP) are variables from indirect measurements that reflect central haemodynamic and arterial stiffness. Family patterns exist [1].

Aim: To investigate if a relationship exists for patterns of central haemodynamics across three related generations, especially c-f PWV.

Methods: In all, 1131 participants from Malmo Diet Cancer Study (MDCS) and Malmo Offspring Study (MOS) were included in this study. c-f PWV was measured in grandparents and in all offspring. Correlation analyses of c-f PWV between offspring and c-f PWV in parents and grandparents were conducted. Parents and grandparents were divided in quartiles by c-f PWV and offspring c-f PWV, and cSBP means were compared with one-way ANOVA analyses. Multiple regression analyses were conducted to adjust for age, sex, BMI, SBP and fasting glucose.

Results: c-f PWV in grandchildren was positively correlated with c-f PWV in parents ($r = 0.26, p < 0.001$) and in grandparents ($r = 0.29, p < 0.001$). Offspring c-f PWV correlated significantly with parental Aix and cSBP. Parents with high c-f PWV had offspring with statistically significant higher means of c-f PWV and cSBP than parents with low c-f PWV.

Conclusion: Measures of central haemodynamics are positively correlated across three generations in a population-based study.

Background: Wave reflection parameters predict cardiovascular events, but 24-hour profiles in large samples of healthy adults are unknown.

Methods: In 1645 individuals free from antihypertensive drugs from 11 centers in Europe and Asia, 24-hour blood pressure monitoring with a validated oscillometric brachial cuff (Mobilograph, I.E.M., Stoolberg; Germany) was performed. Brachial waveforms were acquired and processed with ARCSolver algorithms to derive information relating to wave reflections using pulse waveform analysis (heart-rate corrected augmentation index-AIx75, augmentation pressure-AP) and wave separation analysis (backward wave amplitude-Pb, reflection magnitude-RM). Nighttime/daytime difference (N/D) was nighttime (01.00–06.00) minus daytime (09.00–21.00) values/daytime values. Participants were categorized as young (13–39 years; male/female: 219/112), middle-aged (40–66 years; male/female: 545/553), and old (67–104 years; male/female: 86/130).

Results: 24-hour measures of wave reflections increased with increasing age and were significantly lower in men compared to women (Aix75: 18.3 vs 28.0 %, AP: 10.1 vs 14.9 mm Hg, Pb: 18.9 vs 20.0 mm Hg, RM: 63.0 vs 66.2). Aix75 was higher during daytime compared to nighttime (23.3 vs 21.35), but only in young and middle-aged participants. For all participants, AP (11.6 vs 14.5 mm Hg), Pb (18.5 vs 21.7 mm Hg), and RM (62.9 vs 68.8) were higher during nighttime compared to daytime. N/D varied with age and was more pronounced in younger individuals.

Conclusion: 24-hour variability of wave reflection parameters differs according to age and gender. In future, this information could be useful for tailoring individual cardiovascular risk management.

Objective: The ASINPHAR@2Action programme aims at raising awareness to early vascular aging (EVA) through a community-based intervention. This preliminary analysis is focused on the analysis of the proportion of participants with abnormal arterial stiffness (AS) and the definition of its main determinants.

Design and methods: This preliminary analysis is a cross-sectional, observational, descriptive, non-interventional study of participants enrolled in 11 communal pharmacies in Portugal (HOLON pharmacies), between April and November 2017. Blood pressure (BP) and arterial function parameters were measured with a non-invasive validated device (MOBIL-O-GRAPH, I.E.M.). Clinical and demographic information was gathered.

Background: Dairy products consumption has been related to some metabolic risk parameters. Specifically, some studies have associated higher intake of dairy products with lower pulse wave velocity (PWV) values, although discrepancies persist in this relationship.

Objective: To determine the association between dairy products consumption and PWV.

Methods: A search strategy was conducted in Medline, SCOPUS and WOS, from their inception to June 2018, for observational studies addressing the association between dairy products and PWV. Effect sizes (ES) were estimated by using random-effects meta-analysis models based on Der Simonian and Laird method. Subgroup analyses were conducted based on dairy products type (i.e., milk, cheese, and yogurt).

Results: Six studies were included in this systematic review and meta-analysis. The ES for the association between total dairy products and PWV was −0.01 (95% CI: −0.08; 0.05) (Figure 1). Subgroup analysis could be only performed regarding total dairy products intake of dairy products with lower pulse wave velocity (PWV) values, although discrepancies persist in this relationship.

Conclusions: There was no association between total dairy products, milk, cheese and yoghurt consumption and PWV. Low fat dairy products consumption has been related to lower levels of PWV. These findings add further evidence supporting that dairy products consumption does not pose any additional cardiovascular risk factor. Further research is needed to elucidate the role of each dairy product type on cardiovascular disease risk factors.

Objective: To describe the mean values of different parameters of vascular function, evolution with age and differences by gender in the general population without cardiovascular diseases.

Design and method: An observational, descriptive, cross-sectional study. Study population: From the population assigned to the participating health-care centres, a cluster random sampling stratified by age and gender was performed to obtain 501 participants aged between 35 and 75, 100 per decade (50% women) without cardiac or cerebrovascular disease. Measures: pulse wave velocity femoral carotid (cPWV) was determined using the SphygmoCor System, Cardio Ankle Vascular Index (CAVI) and the pulse wave velocity ankle arm (aaPWV) using the VaSerA.

Results: Mean values: age 55.9 ± 14.2 years (Males = 56.9 ± 14.3y; Females = 54.9 ± 14.2y, p = 0.935); CAVI: 8.0 ± 1.4 (Males = 8.1 ± 1.5; Females = 7.9 ± 1.4, p = 0.043); aaPWV = 12.9 ± 2.7 m/sec (males = 13.2 ± 2.5 m/sec and women = 12.7 ± 2.9 m/sec, p = 0.064) and cPWV: 6.5 ± 2.0 m/sec (Males = 6.8 ± 2.2 m/sec, Females = 6.2 ± 1.8 m/sec, p < 0.001). For each year that the age increases, an increase of the CAVI of 0.073 (y = 0.073*age), in males 0.075 (y = 0.073*age) and in women 0.071 (y = 0.073*age) and an increase in aaPWV of 0.137 m/sec (y = 0.137 m/sec * age), in males 0.118 (y = 0.118 m/sec * age) and in women 0.156 m/sec * age) and an increase in cPWV of 0.092 m/sec (y = 0.092 m/sec * age) in males 0.104 (y = 0.104 m/sec * age) and in women 0.108 (y = 0.108 m/sec * age).

Conclusions: The mean values of CAVI and cPWV as well as the annual increase are greater in males than in females. However, there are no differences in the mean values of the aaPWV and the annual increase is greater in females.
