New chemotherapeutic drugs and radiation therapy have significantly improved cancer patient’s survival, although the cardiovascular (CV) side effects of cancer treatment are increasingly important. In previous studies, an increased risk of cerebrovascular complications such as stroke and transient ischemic attack was described in patients undergoing neck radiotherapy.

Aim: To evaluate vascular carotid structural (IMT, plaque) and functional (carotid stiffness) damage, and changes in arterial stiffness (Carotid-femoral pulse wave velocity; cf-PWV) in Hodgkin Lymphoma survivors previ- ously treated with radiotherapy.

Patients and methods: We enrolled 206 Hodgkin lymphoma survivors (mean age 54 ± 14 years, 51% males, mean follow-up 09 ± 6 years). CV risk factors were investigated and atherosclerotic carotid damage was assessed by standard carotid ultrasound evaluation for intima-media thickness (IMT) measurement (MeanMax-IMT, CBMax, Tmax; n = 167). In 141 patients radiofrequency-based carotid stiffness analysis (distensibility; distensibility coefficient, DC; compliance coefficient; CC) was also performed. Cf-PWV measurement were obtained in 154 patients.

Results: A significant correlation between radiotherapy dose and: MeanMax-IMT (r = 0.20; p < 0.05), Tmax (r = 0.20; p < 0.05), distensibility (r = 0.24; p < 0.05), DC (r = 0.24; p < 0.05), CC (r = 0.24; p < 0.05) was observed. Patients were divided into 4 groups according to radiotherapy dose (Dose: 20–30; 31–36; 37–42; >42 Gy). An increase in Tmax (1.27 ± 0.61, 1.35 ± 0.59, 1.46 ± 0.69, 1.76 ± 1.12 mm, p for trend < 0.05) and in the prevalence of carotid plaque (29%, 31%, 47% and 55%, p for trend < 0.05) was observed as related to dose-category. One-hundred-seventeen patients received neck irradiation (67 bilateral; 50 unilateral). In unilaterally irradiated patients, MeanMaxIMT was greater in the irradiated side as compared to unirradiated carotid artery and the difference reached statistical significance in the group of patients who received a high radiotherapy dose (0.97 ± 0.35 vs 0.92 ± 0.34 p < 0.05). Cf-PWV was significantly greater only in patients that received high dose (>42 Gy), as compared to all the other dose groups (9.7 ± 2.3 vs 8.3 ± 2.8, 8.0 ± 1.5 and 8.3 ± 1.4, p < 0.05).

Conclusions: In this large number of HL survivors, carotid IMT, plaque prevalence and aortic and carotid stiffness were significantly higher in the irradiated carotid arteries, but only at doses >42 Gy, suggesting that there may be a dose threshold for radiotherapy-induced carotid wall damage.

P189 IDENTIFYING PTPN14-DEPENDENT MECHANISMS THAT INFLUENCE CLINICAL MANIFESTATIONS OF HEREDITARY HEMORRHAGIC TELANGIECTASIA
Ons Mamai
UCSF School of Medicine, San Francisco, USA

Hereditary Hemorrhagic Telangiectasia (HHT) is a genetic disorder caused predominantly by loss of a single allele of ENG (HHT1) or ACVRL1 (HHT2). Global incidence is about 1 in 5,000. Clinical manifestations include cutaneous, mucosal and/or gastrointestinal (GI) tract telangiectases that can cause severe epistaxis or GI bleeding. Some patients (10–50%) develop arteriovenous malformations (AVMs) in the lung, brain or liver. We previously showed that genetic variants of PTPN14 (Phospho-Tyrosine Phosphatase Non-Receptor Type 14) genetically associate with the presence of lung AVMs. Homozygous loss of PTPN14 has also been reported to cause lymphedema due to lymph EC hyperplasia.

Other studies, in tumor epithelial cells, show that PTPN14 can dephosphor- ylate b-catenin, modulate HIPPO signaling and regulate tyrosine kinase receptor turnover through endosomal pathways. To investigate its role in ECs and its interactions with the endothelin/ACVRL1 axis, we studied the effect of PTPN14 knock down on differential expression of components of BMP9 and TGF-b signaling pathways in primary human umbilical artery ECs (HUAEC). PTPN14 expression had no effect on pSmad2/3 or pSmad1/5/8 activation but affected protein levels of VEGFR2 and EphrinB2. PTPN14 may thus act on a network of interacting signaling pathways, including endoglin and ACVRL1, by regulating cell surface receptor presenta- tion and endocytic turnover.

Studies are ongoing to address this issue in greater molecular detail. Elucidating the molecular mechanisms involved should contribute to a better understanding of the molecular pathology of HHT, and the regulation of angiogenesis versus stabilization of the vascular bed.

P190 CARDIOVASCULAR DISEASE IN AXIAL SPONDYLOARTHRITIS

Objectives: To estimate the state of the brachiocephalic trunk in patients with axial spondyloarthritis (SpA) and the relationship of changes with the clinical manifestations of the underlying disease.

Material and methods: 55 patients with a diagnosis of axial spondyloarthritis were examined. The average age was 35 ± 0.8 years, the duration of the disease was 5 ± 0.45 years. The criterion for exclusion was the presence of clinical manifestations of diseases of the cardiovascular system (CVS). Control group in the amount of 20 people, corresponding to the sex and age, without clinical manifestations of diseases from the musculoskeletal system and CVS. All patients underwent a duplex study of the brachiocephalic trunk.

Results: Investigation of the intima-media vessel complex (IMC) as an indicator of the thickness of the subendothelial layers of the intima and/or muscle layer of the media is an early marker of the atherosclerotic process. The thickness of IMC was higher in patients with axial SpA (0.75 ± 0.05 mm) compared with the control group (0.68 ± 0.08 mm). The incidence of carotid plaque was higher than in the control group (40% vs. 28%, p < 0.05). The presence of plaque was most often observed in patients with a longer duration of the disease, with hip joint damage, syndesmophytes, a higher limited functional capacity of the joints in the BASFI and BASMI indices.

Conclusion: The asymptomatic course of cardiovascular damage justifies the need for mandatory duplex research of the brachiocephalic trunk patients with axial spondyloarthritis.

P191 AORTIC STIFFNESS AND INFILTRATION IN INFLAMMATORY BOWEL DISEASES: AN INDIVIDUAL PARTICIPANT DATA META-ANALYSIS

Importance: The finding that aortic pulse wave velocity (aPWV) is increased may explain why patients with inflammatory bowel disease (IBD) have an increased cardiovascular risk despite the low prevalence of classic cardiovascular risk factors.

Objective: To determine why these patients have an increased aPWV.

Data sources: A systematic literature search for aPWV in IBD was performed using PubMed, Scopus, Web of Science, and Google Scholar databases.

Study selection: Inclusion criterion was peer-reviewed publications on clinical studies reporting original data.

Data extraction and synthesis: This study followed PRISMA-IPD 2015 guidelines. Data were provided for 4 cohorts in 3 countries (151 patients with ulcerative colitis [UC], 159 with Crohn disease [CD], and 227 controls). Using aPWV, cohort-specific z-scores were calculated after loge-transform and combined in meta-analysis to form pooled effects using a random-effects model.

Results: The pooled z-score was 1.2 m/s. The aPWV was dependent on CD (0.80 z-score [1.0 m/s], 95% confidence interval 0.61–1.00 z-score, p < 0.001)
and UC (β = 0.69 z-score [0.8 m/s], 95% confidence interval 0.49–0.88 z-score, P < 0.001). In patients with IBD, the aPWV was dependent on disease duration (square root years), β = 0.15 z-score, 95% confidence interval 0.02–0.29 z-score, P = 0.03) and white blood cell count (Log[cells/L]), β = 0.48 z-score, 95% confidence interval 0.12–0.84 z-score, P = 0.01) but not on cardiovascular risk factors and therapy.

Conclusions: The increased aPWV reported in this patient population is dependent on inflammation.

Background: The immunosuppressive treatment after organ transplantation highly contribute to evolve cardiovascular comorbidities like hypertension, hyperlipidemia, diabetes and kidney diseases. The effect of hypertriglyceridemia could cause accelerated atherosclerosis. Previous smoking and exessive inflammatory response could increase the cardiovascular risk on those patients who were transplanted because of end-staged chronic obstructive pulmonary disease. Long term follow up needed on lung transplanted (LuTx) patient with cardiovascular risk assessment and to screen patients with vulnerable cardiovascular diseases. However, the correlation between LuTx patients and arterial stiffness is not investigated in the literature.

Method: We investigated the arterial stiffness parameters in 51 LuTx and 49 healthy individuals. The arterial stiffness parameters were measured with oscillometric method (Tensiomed Arteriograph). Aortic pulse wave velocity (aPWV), augmentation index (Aix), central systolic blood pressure (cSBP) and aortic pulse wave reflection time (RT) were determined.

Results: We found increased aPWV and Aix values in lung transplanted (LuTx) patients than in the healthy individuals. Significant higher aPWV (8.45 vs 7.49 m/s; P = 0.045 ) and RT (120 vs 134 ms; P = 0.0004) were found. Patients who were transplanted because of COPD and lung fibrosis the aPWV were significantly higher versus the patient who were transplanted because of cystic fibrosis or pulmonary hypertension.

Conclusion: We strongly recommend the long term cardiovascular follow up on lung transplanted patient, because of the common systemic atherogen effect of the frequent infection and immunosuppressive therapy.

CAROTID ATHEROSCLEROSIS, AORTIC STIFFNESS AND PENILE VASCULAR DAMAGE IN PATIENTS WITH ERECTILE DYSFUNCTION: RELATION TO LOW DENSITY LIPOPROTEIN LEVELS AND STATIN THERAPY
Nikolaos Ioakeimidis, Charalambos Vlachopoulos, Athanasios Angelis, Dimitrios Terentes-Printzios, Chistos Georgakopoulos, Konstantinos Aznaouridis, Iosif Koutagiar, John Skoumas, Skliros, Dimitrios Tousoulis
1st Dep of Cardiology, Hippokration Hospital, Athens Medical School, Greece

Purpose/Background/Objectives: Aim of the study is to examine the possible differentiation of aortic stiffness, carotid atherosclerosis and penile vascular function among patients with erectile dysfunction (ED) according to cholesterol level and statin therapy.

Method: We measured carotid intima-media thickness (IMT), carotid-femoral pulse wave velocity (PWV) and penile peak systolic velocity (PSV) 20 min after intracavernous injection of prostaglandin E1 in 356 consecutive ED patients (mean age 57 ± 9 years). Lipid parameters and total testosterone were measured in all patients.

Results: 95 (26.7%) ED patients are treated with statins. The patients not receiving statin therapy (n = 261) were subsequently divided into three groups according to LDL level (group 1: LDL < 100 mg/dl, group 2: LDL: 100–155 mg/dl, group 3: LDL > 155 mg/dl).

Patients with statin therapy and subjects in group 2 have similar mean LDL level. Carotid IMT was higher in patients with LDL >155 mg/dl (group 3) compared to patients treated with statins (P = 0.01) and subjects with LDL: 100–155 mg/dl (P = 0.005) and LDL < 100 mg/dl (left plot, P < 0.001).

Conclusions: Although treated hypercholesterolemic patients exhibited lower atherosclerotic burden compared to untreated individuals with high LDL levels, penile blood inflow remains significantly impaired.
