Abstract—Under the background of the catenaries of the second double line of Lan-Xin Railway in strong wind zone, we established the finite element mode of the four-span structure with catenary, and compared the value of model elastic to verify the correctness. Besides, we get some useful conclusions from the comparative study of the static and dynamic wind performance of the simple catenaries and elastic catenaries, providing the theoretical support to the catenaries design.

Keywords—catenary; wind-induced vibration; strong wind zone; finite element model

I. INTRODUCTION

The second double line with a full-length of 1776km of Lan-Xin Railway which cross Gansu, Qinghai and Xinjiang Province goes through the Beacon Anxi wind zones in Gansu and Yandun, Baili, Sanshili and Dabancheng wind zone in Xinjiang. These wind zones are total 540km.

In the area of high wind, wind speed, maximum wind speed exceeds 60m/s, the wind long, seasonal strong, steady wind, the wind blows faster, especially Barry wind zone ten miles, is one of the most powerful wind in inland areas. Gale has repeatedly caused both Portland and new southern railway overturned wheel stop. It has brought into huge economic losses and serious social impact.

As the important infrastructure electrification of the railway, the security, stability and fatigue resistance of catenaries are greatly influenced by strong winds [1]. Under the action of high wind, the catenary will move with violently vibration, affecting the pantograph high speed dynamic performance quality and shortening the life of the catenary, and even leading to the accident of pantograph-catenary. In the area with breakwind, the gale growth area appears on the breakwind and the vortex area appears after the breakwind, which can increase the movement and vibration of catenary. It will has a greater impact on the security stability and fatigue resistance of catenary, and bring bad security threat to the high-speed railway. Currently, there is little mature experience and theory in china and abroad about the result of catenary movement and vibration[2]. By theoretically analyzing, choosing the catenary with better wind resistance can provide crucial scientific evidence for the construction of the second double-track Lan-xin catenaries.

According to the case of previous studies on the peripheral wind speed distribution, we analysis the wind-induced response of catenaries with the method of theoretical analysis, which provide the evidence to the choosing of the form of an elastic suspension or simple suspension and determine the direction of the catenary design[3].

II. CALCULATION MODEL

A. Calculation Model Overview

This paper selects a straight-shaped straight section on the suspension, and deemed fully compensated catenary, in the analysis, the tensions of load-bearing wire and contact wire catenary contact lines are constant. The model contains 4×50m elastic catenary (German) and simple catenary (Japan) [4]. Droppers arrangement is shown in Fig.1 and Fig.2.

Figure 1. Bomb droppers chain suspension arrangement
Controlling parameter structure is the lateral limits of 3.15m; stagger 0.25m, structural height 1.6m, simple chain (Japanese) for the elastic chain (Ashkenazi) 0.95m. The main design parameters of the structure as shown in Table I.

B. Catenary Flexible Computing and Verification

The results herein catenary elasticity finite model calculation results with existing literature and empirical comparison; verify the correctness of the finite element model by the contrast.

### a. The elastic calculation results of wind-induced vibration model

The results herein catenary elasticity finite model calculation results with existing literature and empirical comparison; verify the correctness of the finite element model by the contrast.

\[
\eta = \frac{l}{4T_c + T_T}
\]

Where \( \eta \) - suspension point elasticity; \( l \) - span length (m); \( T_c \) - catenary tension (kN); \( T_T \) - contact wire tension (kN).

### b. Elastic literature and empirical formula calculation

According to "high-speed electrified railway catenary" (Yu Wan-ju)[5]: Germany Re250 and Re330 type catenary type elastic computing, its simple chain span at the center of the elastic suspension is calculated as:

\[
\eta_{\text{emp}} = \frac{l}{3.5(T_c + T_T)}
\]

Its elastic chain elastic suspension span is calculated at the center of:

\[
\eta_{\text{emp}} = \frac{l}{3.5(T_c + T_T)}
\]

### c. Flexible comparison results

This paper established a simple chain, wind-induced vibration model bomb chain force balance established by the locator model, the intent was more realistic catenary wind-induced vibration simulation.

Wind-induced vibration finite model and finite comparison; verify the correctness of the finite element model by the contrast.
element model of the existing literature comparing the resulting simplified chain, same bullet chain variation trend is resilient[8]; and empirical and comparative literature, contacts the gateway key parts of elastic computing results are basically the same as in Table II.

The results from the perspective of flexibility, this model of wind-induced vibration limited scientific.

III. CALCULATION OF STATIC WIND

A. Static Load

According to aerodynamic theory, the role of the contact line of force size[9]:

$$F_d = \frac{1}{2} \rho UdLc_z$$  (3)

Where: $\rho$ is the air density, $D$ is the diameter of catenary, droppers and contact line, $L$ is the length, $c_z$ of the contact line, drag coefficient catenary and hanging string. $U$ as in catenary height wind speed can be calculated by the following formula, namely: $U = K \times U_{10}$

(4)

Where $U_{10}$ is the wind speed from the surface 10 meters at a height, $H$ for the catenary height of each point from the ground. It is the surface roughness index, where take 0.16. $K$ for the installation of a wind screen (wall) after catenary height wind speed reduction factor. When there is no windshield $K = 1.0$.

According to the wind screen hole test results, catenary wind speed amplification factor of 1.12, the wind attack angle 16.8°, the drag coefficient wind axis is 0.8. According to the results of the wind screen hole test, the wind speed reduction factor of the contact line of 0.76, angle of attack of 13.7°, the drag coefficient air shaft 0.77. In the calculation process for security purposes, the contact line of wind speed reduction factor of 1.0.

B. Calculation of Static Wind

Fig.7 and Fig.8 horizontal displacement means the displacement direction perpendicular line, measured from the centerline of the line, the right level of positive vertical displacement of vertical displacement, measured from the contact line design position, upright is positive. Calculations show that, compared with the simple elastic chain chain, average wind partial elastic chain chain than simply big.

Figure 7. Simple horizontal and vertical chain contact line deviation

Description: horizontal deviation refers to the horizontal distance from the center line deviation to the right level is positive. Vertical lift means the contact line design deviates from the vertical height of the distance in the vertical direction is positive. At a distance of 0m positive locator at the distance ±50m at anti locator place[10].

IV. FLUCTUATING WIND DYNAMIC ANALYSIS

A. Overview of The Three-Dimensional Numerical Simulation of The Wind Spectrum

Natural wind in time and space are random, structural wind analysis generally be regarded as approximate dimensional multivariate each state through a stationary Gaussian process. This paper wind spectrum simulated using spectrum solution. Spectrum solution is characterized by a simple algorithm, theoretical perfect consistency of each state Gaussian their samples, mean and correlation function, mean and correlation function characteristics are obtained through mathematical proofs, simulation results are more reliable.

Vertical wind profile line selection Simiu wind speed spectrum:

$$S_v(\omega) = \frac{100Z_0^2}{\pi U(Z)\left[1 + 25\alpha Z\left[\pi U(Z)\right]\right]^2}$$  (5)

Vertical wind profile selection Lumley-Panofsky wind speed spectrum:

$$S_v(\omega) = \frac{3Z_0^2}{\pi U(Z)\left[1 + 2\alpha Z\left[\pi U(Z)\right]\right]}$$  (6)

Using WAWS for selected stationary Gauss random process wind spectrum simulation of n-dimensional wind field spectrum.

B. Catenary Fluctuating Wind Power History Analysis

The dynamic analysis is based on the previous stage linear analysis performed[11], the simulation time step 1/48s, modal damping ratio of 0.5%, a total of 9999 times the full method transient analysis. Partial results shown in Fig. 9 to Fig.10.

V. CONCLUSION

1. As can be seen from the list of data, consider column wrist and other support systems flexibility and elasticity of this support does not consider the results of the static wind analysis system has little effect[12].

2. by a simple chain, bomb chain lateral deviation can be seen, when the wind speed between 25m/s ~ 40m/s maximum deviation of the position is still at the front and back setter, when the wind speed at 50m/s~65m/s of time position of maximum deviation from the anti-locator shift at the mid-span, the wind speed is higher, the maximum deviation from the position closer to the span.

3. by a simple chain, bomb chain vertical uplift can be seen, the maximum lifting distance in cross or across the neighborhood. Uplift uplifting than simple elastic chain more even more.

4. The maximum displacement summary charts and contact line can be seen from the time history, on power issues, structural height and structure of highly elastic chain 1.6m 0.95m Jane, in the case of other design parameters consistent, contact line vibration displacement difference is small.
