Keywords: Rotation matrix; forward kinematics; inverse kinematics; robot workspace

Abstract. The improved kinematics method based on the orthogonality of rotation matrix and matrix block is presented for MOTOMAN - HP20 robot to improve the computing speed of the robot kinematics. Firstly, according to the robot structure, the forward kinematics model is established with D-H method. And for the inverse kinematics, the separation method of position and orientation matrix is used to transform complex matrix equation into eight algebraic equations to improve the computing speed. For extraneous roots, the optimal solution is confirmed by selecting the closest one to the current joint angle with the solving order directly, instead of computing all the roots. Finally, the workspace is obtained by the simulation and the kinematics analysis method is proved to be efficient.

1. Introduction

For the kinematics analysis, the forward kinematics equation is generally established by D-H kinematics parameters, but the inverse kinematics is more complicated, and there are some popular methods, e.g. the matrix transformation method based on D-H parameters [2]. Matrix transformation is widely applied, but the method needs more homogeneous transformation matrix inversion and repeatedly multiplication by inverse matrix. Another method is geometric method for the robot structure [3]. Although it has the advantage of fast operation speed, it is limited by the structure of the robot. Screw transformation and quaternion method [4] is more complicated. Neural network [5], genetic algorithm [6] etc. also have been used to the inverse kinematics. But the stability and precision are still unable to meet the requirements of real-time control. So some modified methods have been proposed to improve the operation rate of matrix transformation method [7-8]. The vector operation of a nonlinear equation [9] was also proposed to solve the inverse kinematics problem.

For MOTOMAN-HP20 robot, an inverse kinematic method is presented to avoid inverse computation of large-scale matrices based on the orthogonality theory of the rotation matrix, homogeneous matrix is decomposed into rotation matrix and position matrix, the inversion for the matrix is transferred into transposition operation, improving the solving efficiency. And according to the principle of "minimum distance" for each joint angle, the optimal solution of the inverse kinematics is selected to avoid solving extraneous roots. Finally, the robot workspace was obtained by simulation, and the kinematics method is verified to be correct.

2. Forward kinematics analysis

MOTOMAN - HP20 is six degrees of freedom (6 DOF) serial chain robot with a spherical wrist. The coordinate system is shown in Fig.1.

Fig.1 The coordinate system of MOTOMAN-HP20
Robot D-H parameters are shown from Table 1.

Use the homogeneous matrix of D-H to describe the coordinate transformation matrix of two adjacent links, the matrix \([9]\) can be expressed as

\[
    _{i-1}^iT = \begin{bmatrix}
    \cos \theta_i & -\sin \theta_i & 0 & a_i \\
    \sin \theta_i \cos \alpha_i & \cos \theta_i \cos \alpha_i & -\sin \alpha_i & -\sin \alpha_i \, d_i \\
    \sin \theta_i \sin \alpha_i & \cos \theta_i \sin \alpha_i & \cos \alpha_i & \cos \alpha_i \, d_i \\
    0 & 0 & 0 & 1
    \end{bmatrix}
\]

where \( a_i \) is the link length, \( d_i \) is the distance between adjacent link, \( R_i \) is a 3x3 rotation matrix:

\[
    R_i = \begin{bmatrix}
    \cos \theta_i & -\sin \theta_i & 0 \\
    \sin \theta_i \cos \alpha_i & \cos \theta_i \cos \alpha_i & -\sin \alpha_i \\
    \sin \theta_i \sin \alpha_i & \cos \theta_i \sin \alpha_i & \cos \alpha_i
    \end{bmatrix}
\]

\( P_i \) is a 3x1 position sub-matrix as

\[
    P_i = [a_i; -d_i \sin \alpha_i; d_i \cos \alpha_i]
\]

Then the kinematics equation can be

\[
    _0^T = _0^T _1^T R_1^T R_2^T R_3^T R_4^T R_5^T = \begin{bmatrix}
    R & P \\
    0 & 1
    \end{bmatrix}
\]

where \( _0^T \) is the pose matrix; \([P_x, P_y, P_z]^T\) is the position vector, \([n_x, n_y, n_z]^T\), \([a_x, a_y, a_z]^T\), \([a_x, a_y, a_z]^T\) are respectively orientation vector of the coordinate system of the end operator relative to the x, y and z axis of the reference coordinate system.

By the D-H parameters in Table 1 with the Eq.(1), the homogeneous transformation matrix between the adjacent links can be written as

\[

   _0^T = \begin{bmatrix}
    \cos \theta_1 & -\sin \theta_1 & 0 & 0 \\
    \sin \theta_1 \cos \alpha_1 & \cos \theta_1 \cos \alpha_1 & -\sin \alpha_1 & 0 \\
    \sin \theta_1 \sin \alpha_1 & \cos \theta_1 \sin \alpha_1 & \cos \alpha_1 & 0 \\
    0 & 0 & 0 & 1
    \end{bmatrix}
\]

\[

   _1^T = \begin{bmatrix}
    \cos \theta_2 & -\sin \theta_2 & 0 & 150 \\
    \sin \theta_2 \cos \alpha_2 & \cos \theta_2 \cos \alpha_2 & -\sin \alpha_2 & 0 \\
    \sin \theta_2 \sin \alpha_2 & \cos \theta_2 \sin \alpha_2 & \cos \alpha_2 & 0 \\
    0 & 0 & 0 & 1
    \end{bmatrix}
\]

\[

   _2^T = \begin{bmatrix}
    \cos \theta_3 & -\sin \theta_3 & 0 & 760 \\
    \sin \theta_3 \cos \alpha_3 & \cos \theta_3 \cos \alpha_3 & -\sin \alpha_3 & 0 \\
    \sin \theta_3 \sin \alpha_3 & \cos \theta_3 \sin \alpha_3 & \cos \alpha_3 & 0 \\
    0 & 0 & 0 & 1
    \end{bmatrix}
\]

Then \( n, o, a, p \) can be derived in \( x, y, z \) index.

3. Inverse kinematics solution

3.1 Inverse kinematics method

The inverse kinematics of the robot is the process to compute joint angle of each link based on given pose of end-effector operator, which plays an important role in the robot control system. The condition that the robot existing a closed form solution of inverse kinematics is to meet one of two
conditions of Pieper criteria [11] for the robot’s mechanical structure: (1) The axes of three adjacent joint need to intersect to one point; (2) The axes of three adjacent joint are parallel to each other. The mechanical structure is designed with the axes of the three adjacent joint intersect, so the closed-form solution exists. Transformation matrix with the two adjacent link as Eq.(1) is divided into rotation matrix and position matrix, with inverse rule of partitioned matrix the rotation sub-matrix is orthogonal matrix, it meets $R_i^{-1} = R_i^T$. Thus,

$$
(-^iT)^{-1} = egin{bmatrix}
R_i^T & -R_i^TP_i \\
0 & 1
\end{bmatrix} (i = 1, 2, \ldots, 6)
$$

Therefore, inversion computation of the rotation matrix is converted to compute transpose. Thereby, the amount of calculation significantly is reduced. To find the inverse kinematics solution, link transformation equation can be rewritten as

$$
R_{i+1}^T R_{i} T = R_{i-1}^T R_{i+1} T R_{i} T + R_{i-1}^T R_{i} T R_{i} T R_{i} T
$$

The left and right matrixes of Eq.(6) are

$$
\begin{bmatrix}
c_1 c_3 - s_1 s_3 & c_1 c_2 s_2 - c_2 s_3 & -c_3 s_2 s_4 - s_3 c_4 & 140c_1 s_1 + 795s_3 + 760 \\
-s_2 c_4 c_5 + s_5 & -s_2 c_4 s_5 + c_5 & c_4 s_5 & 140s_3 - 795c_3 \\
s_2 c_4 c_5 + s_5 & s_2 c_4 s_5 + c_5 & -c_4 s_5 & 0 \\
0 & 1 & 0 & 0
\end{bmatrix}
$$

Considering the structure characteristics, the first three joint angles ($\theta_1$, $\theta_2$, $\theta_3$) are used to decide the position of the end-effector, and then the last three joint angles ($\theta_4$, $\theta_5$, $\theta_6$) determine the orientation of the end-effector, so the solution of the inverse kinematics can be decomposed into the position and posture matrices. For the left and right sides of Eq.(6) are equal, and the equations for the first three joint angles can be derived by the corresponding element in the position sub-matrices, and by the posture matrix, five equations for the last three joint angles can be obtained. Suppose $c_i = \cos \theta_i$ and $s_i = \sin \theta_i$, then the equations are as follows:

$$
s_1 p_x - c_1 p_y = 0
$$

$$
c_2(p_x c_1 + p_y s_1 - 150) + p_y s_2 = 795s_5 + 140c_1 + 760
$$

$$
s_2(p_x c_1 + p_y s_1 - 150) + p_y c_2 = 140s_3 - 795c_3
$$

$$
-c_3(c_2 + c_5 c_4) - s_2 s_4 c_5 = -c_5 c_4 s_3 - c_3 c_4
$$

$$
s_3 c_a + s_2 a_x = -s_3 c_x s_4 + c_3 c_4
$$

$$
s_3 c_a + c_2 a_x = -s_3 s_x s_4
$$

$$
(c_1 n_y - s_1 n_x) c_y + (s_1 n_y - c_1 n_x) s_y = -s_4 c_1
$$

By solving the above eight equations, various joint angles can be shown as follows:

$$
\theta_1 = A \tan 2(p_x, p_y) \text{ or } A \tan 2(-p_x, -p_y)
$$

$$
\theta_2 = A \tan 2(h_3, p_z - h_i h_4, h_i h_3 + p_z h_4)
$$

$$
\theta_3 = A \tan 2(h_2, \sqrt{1 - h_2^2}) - A \tan 2(140, 795) \text{ or } A \tan 2(h_2, -\sqrt{1 - h_2^2}) - A \tan 2(140, 795)
$$

$$
\theta_4 = A \tan 2(c_1 a_x - s_1 a_x, a_z s_3 c_4 + c_3 (c_2 a_x + s_2 a_x)) \text{ or } A \tan 2(140, 795)
$$

$$
\theta_5 = A \tan 2(s_3 c_1 (s_5 c_4 - c_5 n_y), s_3 c_2 - s_1 c_3 c_4 (s_1 n_y - c_1 n_x))
$$

where $h_1 = p_x c_1 + p_y s_1 - 150$, $h_2 = (h_1^2 + p_z^2 - 140^2 - 795^2 - 760^2) / 1520 \sqrt{140^2 + 795^2}$, $h_3 = 140c_3 + 795s_3 + 760$, $h_4 = 140s_3 - 795c_3$, $g = s_3 (c_2 a_x + s_2 a_x) - c_3 a_x$.

### 3.2 Choosing method of the optimal solution

For any given end-effector pose, there are eight groups of inverse solution. But only a set of definite solution is needed, so choose the closest solution to the last angle from multiple sets of inverse solution within the scope of the joint movement. In general, the optimal solution of inverse is selected after the inverse solutions of all the joint angles are calculated, and the optimal set among all the inverse solutions is that the sum of all the joint angles is smallest. It can be expressed as

$$
\min S = \min \sum_{i=1}^{6} | \theta_i - \theta_s |
$$

But this method requires to compute all the solutions, and then to determine a set of the optimal
solution. To reduce the motion time and ensure the least change of the joint angle from the current pose to the next pose, only make sure that the change value of every joint angle is minimum, and the change sum of all angles is minimum. Therefore in the process of computing the joint angles of inverse kinematics, for the joint angles that exist multiple solutions, firstly, to estimate whether the value of these joint angles is within the allowed scope, then by \( \min |\theta_i - \theta_{i0}| \) to determine the most optimal solution, using the optimal solution to calculate the next joint angle and determine the minimum value of the next joint angle by the same way.

4. Simulation and verification of kinematics

4.1 Simulation of the robot workspace

Workspace is an important kinematics indexes for assessing the robot ability to work. The most common method to calculate the workspace is the monte-carlo method [11], the cycle strategy is used to calculate the robot workspace in this paper. The position vector of robot end-effector is given in Eq.(14), the scope of the workspace is determined by the position vector, according to \( p_x, p_y, p_z \) and the scope of the robot joint angle to determine the robot workspace. The specific steps are:

1. The position vector:
   \[
   p_x = 140c_1c_23 + 795c_1s_23 + 760c_1c_2 + 150c_1, \quad p_y = 140s_1c_23 + 795s_1s_23 + 760s_1c_2 + 150s_1, \quad p_z = 140s_23 - 795c_23 + 760s_2, \]

2. The range of the joint angle is as follows:
   \[
   (-\pi \leq \theta_1 \leq \pi), \quad (-\frac{11}{18}\pi \leq \theta_2 \leq \frac{31}{36}\pi), \quad (-\frac{11}{12}\pi \leq \theta_3 \leq \frac{17}{12}\pi), \quad (-\frac{10}{9}\pi \leq \theta_4 \leq \frac{10}{9}\pi), \quad (-\frac{5}{18}\pi \leq \theta_5 \leq \frac{23}{18}\pi), \quad (-2\pi \leq \theta_6 \leq 2\pi) \]
   all the end-effector coordinates within the change scope of the joint angle can be obtained.

3. The workspace result is shown in Fig.2.

4.2 Verification of the robot kinematics

Firstly, a motion trajectory is given. The trajectory within 0s to 50s:
   \[
   p_x = \sin(t); \quad p_y = 10\times(\sin(t)) + 670; \quad p_z = 10\times(1-\cos(t)) + 415 \]
   from Fig.3(a). Secondly, keep the orientation of the robot end-effector as \( R = [0 1 0; 0 0 1; 1 0 0] \). According to solving inverse kinematics of MOTOMAN-HP20, the changes of the six joint angles are shown in Fig.4. By the forward kinematics equation, the position vector can be obtained. The simulation trajectory of the manipulator is shown in Fig.3(b). Finally, comparing with the result of Fig.3(a) and Fig.3(b), the trajectory curve by the forward kinematics equation is the same as the curve space given in Fig.3(a), the correctness of the forward and inverse kinematics solution can be verified in this work.

![Fig.3](image)

Fig.3 (a) The given space spiral curve; (b) The trajectory of the forward kinematics
The kinematics of MOTOMAN - HP20 robot was studied in the paper, and a kind of method about the kinematics analysis based on rotation matrix orthogonality and matrix block thought is put forward. By the simulation, the robot workspace is calculated, and the correctness of the forward kinematics solution and inverse kinematics model is given to provide the theoretical foundation for the research of robot control and trajectory planning optimization. This method can also be used to provide the kinematics reference for other industrial robot with six-degree-of-freedom.
