Keywords: waste mercury catalyst, PVC production, recovery of mercury

Abstract. Serious pollution of waste gas, waste water and waste residue are generated by calcium carbide-based polyvinyl chloride (PVC) production in China, especially the mercury pollution on account of using a mass of mercury chloride catalyst (HgCl\textsubscript{2}). This study introduced main methods and techniques which were grouped into fire metallurgy and hydrometallurgy respectively for recycling mercury from waste mercury chloride catalyst of PVC production. The different process conditions and recovery effect of mercury of these methods were illustrated in this paper.

Introduction

Mercury is one of the most hazardous metals because of its ability to evaporate in soil or water. It is extremely dangerous\cite{1}. 3600t mercury worldwide enter into the environment each year. Mercury emissions mainly comes from the two parts of natural and artificial sources. Natural source mainly comes from the natural release by geological source. Artificial sources refers to mercury emissions, including the use of mercury, mercury content of impurities and waste mercury disposal such three categories. China is now the largest source of mercury emissions. China emits at least 700 t of mercury per year, mainly from coal combustion, metal smelting, and cement production, which is 1/4 of the global emissions\cite{2}.

Mercury chloride catalyst produced by PVC production is one of the largest mercury consumption. Unlike other countries, most of PVC (80.9\%) produced in China is made though the calcium carbide process because China has larger source of coal than oil. It has been estimated that to produce 1 t of PVC through the calcium carbide process used 1 kg-2 kg of mercury-impregnated catalyst is consumed. 700 t -1200 t mercury chloride catalyst has been consumed by calcium carbide process in 2009, but 50\% of the mercury chloride cannot be recycled\cite{3}. And according to our knowledge, there is few report about the review of recycling mercury from waste mercury chloride catalyst of PVC production systematically and detailedly up to now.

The aim of this paper is to summarize the methods of recycling mercury from waste mercury chloride catalyst and provide research foundation for new methods and techniques of recycling mercury source.

Ways of mercury flow and emissions in PVC production

There are four main ways of mercury flow and emissions:\textsuperscript{1}waste mercury chloride catalyst; \textsuperscript{2}waste activated carbon; \textsuperscript{3}waste hydrochloric acid; \textsuperscript{4}translating into sublimation mercury. The possession proportion to used mercury chloride catalyst were shown respectively in table 1.

The mercury chloride catalyst normally contains 10.5%-12.5% HgCl₂, which can sublimate out quite a number of HgCl₂ which react with acetylene and generate Hg₂Cl₂ under the transformation temperature of 180 °C⁴. Hg₂Cl₂ will produce serious harm to water resource. Sublimation HgCl₂ will react with hydrogen and generate Hg⁰ at the same time. It is very deadly that Hg⁰ will be vented to atmosphere when catalyst was replaced. The solution is to use low-mercury catalyst and non-mercury catalyst. Low-mercury catalyst contains 5%-6.5% HgCl₂ and is not easy to sublimate out HgCl₂ under temperature of 180 °C⁵. Many attempts have been made to research and development new-type non-mercury catalyst at home and abroad.

Another main flow and emitters of mercury is waste mercury chloride catalyst which is substituted from the front desk for catalytic converter when acetylene conversion rate less than 75%. Waste mercury chloride catalyst has adsorbed a large amount of hydrogen chloride gas, as a result the aqueous solution is strongly acidic and mercuric. It is a highly toxic and corrosive waste, mercury is in commonly 2% to 5%, a small number of as high as 8%. Therefore, recovering mercury and other useful materials from waste mercury chloride catalyst is far-reaching significance to environment and resources.

Methods of recycling waste mercury chloride catalyst

The recovery process can be divided into two major categories of fire metallurgy and hydrometallurgy.

Fire metallurgy method. The traditional fire metallurgy process is that using waste mercury chloride catalyst soak or boil hot with 10% ~ 15% NaOH or 15% Na₂CO₃ or lime (calcium oxide of 20%). So HgCl₂ is transformed into HgO. And then put HgO in metal cans, heat indirectly to 700 °C ~800°C, making it to mercury vapor and recycling metal mercury via condensation. The reaction mechanism is as follows⁶:

\[
\begin{align*}
\text{HgCl}_2(aq) + \text{NaOH}(aq) & \rightarrow \text{Hg(OH)}_2(s) + 2\text{NaCl}(aq) \\
\text{Hg(OH)}_2(s) & \rightarrow \text{HgO(s) + H}_2\text{O} \\
2\text{HgO(s)} & \xrightarrow{\Delta} 2\text{Hg(g) + O}_2(g) \\
\text{Hg(g)} & \overset{\text{Condensation}}{\rightarrow} \text{Hg(s)}
\end{align*}
\]

Although this process has been industrialized production, but mercury recovery rate is only about 65%. There are still many technical problems that high energy consumption, escaping risk of mercury vapour, dust combined with mercury need to be solved. At present, carbonization method charging with oxygen of recycling waste mercury chloride catalyst is the most advanced new technology⁷,⁸ Recovering HgCl₂ directly from activated carbon to avoid many disadvantages, such as low recovery rate and complex conversion process. The overall recovery efficiency of HgCl₂ can reach above 99%. But carbonization method charging with oxygen is still patented technology. On the Other hand, it is an arduous task that upgrading and the operation cost of production equipment is expensive for many small and medium-sized enterprise of PVC production by calcium carbide.

Hydrometallurgy method. Recycling waste mercury chloride catalyst by hydrometallurgy method do not use conventional high temperature roasting or heating furnace, and recycle metal mercury or other useful components in the solution. Many new recycling technology is developing. It is also a research hotspot that adopting pretreatment, solidification/stabilization or chemical activation method to recycle Hg and other useful material from waste mercury chloride catalyst.

Such as Yunren Qiu⁹ used acidification-ultrasound recycling waste mercury chloride catalyst. The product can be used for mercury catalyst preparation and the process is high efficiency, low energy consumption. Zailiu Yuan¹⁰ invented a method which made waste mercury catalyst had more application, there was no waste water discharge, low energy consumption and mercury recovery rate of 97% or more through the combination step of soaking, alkaline leaching, reduction and filtering.
Guangren Yu\textsuperscript{[11]} dealt with the mercury waste chloride catalyst by pretreatment of using functional solvent I for removing impurity, and extracting Hg(II) and mercury compound with functional solvent II. The recovery of Hg was over 99.9%, solvent I and solvent II all could recycle, and mercury content in the catalyst was less than 0.01%. Jianxin Zhu\textsuperscript{[12-13]} added sodium sulphide for additives by means of mechanical ball mill to solidify and stabilize waste mercury catalyst. Mercury leaching value was lower than the United States environmental protection standard limit of 0.2 mg/L of hazardous wastes and the Chinese national hazardous waste identification standard limit of 0.1 mg/L. The specific circumstances of the above several patents as shown in table 2.

Such a large number of studies have shown that it is essential to recycle mercury resources though continuous research of new type solidifying and recycling process.

**Summary**

The recycling methods of mercury from waste mercury chloride catalyst are introduced in this paper. The methods mainly include fire metallurgy and hydroetallurgy. Traditional fire metallurgy is mature but the effect of mercury recycling is low and severe pollution. New fire metallurgy has high recovery of mercury and less pollution but spreading the method is still restricted. Hydroetallurgy method is a hot spot in recent research which has diversity of production mode, low energy consumption and strong maneuverability. In the current serious situation of shortage of mercury resources, reduce mercury resources consumption and waste, increase resources recycling are the trend. New recycling process can undoubtedly reduce the waste of mercury resources and establish integrated recycling equipment to make the PVC industry more clear and controllable.
