\textbf{Keywords:} Electric car; Finite element model; Strength analysis; Stiffness analysis; Modal analysis

\textbf{Abstract.} This paper used SolidWorks to design pure electric car structure, and interfaced into the ANSYS through the graphical data conversion. The finite element model of the vehicle is generated by grid division. The finite element analysis of the vehicle body is carried out. The strength and stiffness characteristics of the vehicle body under different working conditions are calculated in the static analysis. The frequency of the vehicle body is calculated by modal analysis.

\textbf{Introduction}

Pure electric vehicles are considered to be the future of the car. It has the advantage as follow: low emissions, less pollution, relatively simple structure and lightweight. The researches are in this field, such as Rinspeed company\cite{1} published a small electric car, which is called "eXasis". The car body is made of a transparent design, and used frame body and body structure of high tech plastic panel. Wang et. al. \cite{2} designed the layout of car body. Lei and Xiao \cite{3} carried out the conceptual design and topology optimization design of pure electric vehicles under many working conditions. After the model is built, 40\% of the head shell is subjected to finite element analysis. Finally, the deformation head is optimized to achieve the crushworthiness of the vehicle body and the lightweight is designed. Botkin \cite{4} adopted the topology optimization method to achieve the optimization goal of automobile structural design by re-distributing the material in the structure. Nagesh \cite{5} et. al. explored the NVH performance of pure electric vehicle. It includes noise, vibration, and harshness. Zhu et.al. \cite{6} explored the dynamic behavior of three distinctive types of automobile. They used ANSYS to simulate the modal analysis of the vehicle frameworks and introduced the vibration and the resonance behavior of localizations.

The intention of this paper is to design a pure electric car according to the dynamic parameters of a predetermined location. On the basis of meeting stiffness and strength requirements, lightweight design is achieved, and vibration analysis is performed.

\textbf{Theories Analysis}

In this paper, the VonMises criterion is used to determine whether the body strength conforms to the strength requirement. Whether the maximum stress is taken by the car body or whether it is within the allowable stress range of the material. Bending rigidity of car body is

$$K_B = \frac{W}{D}$$

where \(W\) is the total load applied, \(D\) is the maximum vertical deflection. And, torsional rigidity of car body is

$$K_T = \frac{FL}{\theta}$$

where \(F\) is the vertical load applied to the front suspension, \(L\) is the pure electric car body wheelbase, \(\theta\) is the relative rotation angle of car body.
Because the structure of body structure of pure electric car was very complex, we should simplify the structure first. This paper exports the equations of the system.

\[
[M]\ddot{X} + [K]X = 0 \tag{3}
\]

Defined the position vector \{X\} as \{Δ\}u, where \{Δ\} was the modal matrix of the system. Eq. (3) could be changed as follow:

\[
[I]u + [A]u = 0 \tag{4}
\]

In which:

\[
\begin{bmatrix}
1 & 0 & \cdots & 0 \\
0 & 1 & \cdots & \vdots \\
\vdots & 0 & \ddots & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
Δ_1 \\
Δ_2 \\
\vdots \\
Δ_n
\end{bmatrix}
= [I]
\]

\[
\begin{bmatrix}
\omega_1^2 & 0 & \cdots & 0 \\
0 & \omega_2^2 & \cdots & \vdots \\
\vdots & 0 & \ddots & 0 \\
0 & \cdots & 0 & \omega_n^2
\end{bmatrix}
\begin{bmatrix}
Δ_1 \\
Δ_2 \\
\vdots \\
Δ_n
\end{bmatrix}
= [A]
\]

The natural frequency of the mistuned system was expressed as follow:

\[
\bar{\omega}_n = \frac{\omega_n}{\sqrt{EI/\rho AL^2}}, n = 1, 2, 3, \ldots \tag{7}
\]

**Finite Element Modeling**

This paper imported the 3D geometry model built in SolidWorks into ANSYS, as shown in Fig. 1. The pure electric car designed into account the lightweight factors in this paper takes. Table 1 shows the design parameters of pure electric car. The aluminum alloy is taken as the material for the body structure, and the specific parameters are shown in the following table 2. After the mesh is divided, the finite element model is shown in Figure 2. The model contains 114126 elements and 185284 nodes. The element types are choice 3D hexahedral solid elements.

Static Analysis

Loading mode of automobile body in bending condition is shown in Fig.3. The boundary condition is the degree of freedom of all supporting seats to restrain the X, Y and Z directions before and after the constraint. The load condition is given 4000N concentrated force on the center of the seat.

By solving the ANSYS processor, the deformation of strain and stress under bending conditions can be obtained, as shown in figures 4(a) and 4(b).
According to the calculation results of the deformation diagram, the maximum stress value of the body under bending condition is 28.204 Mpa. The result is lower than the yield strength of aluminum alloy, and meets the requirements of strength. And through the body deformation diagram, we could get that the maximum deformation occurs at the front of the body floor is 0.73mm and bending stiffness is 5479 N/mm.

The loading of the car body in torsion is shown in Fig. 5. The translational freedom of the X and Y directions is restrained at the rear support seat, and the Y axis load concentrated force 2000N with the same magnitude and opposite direction is applied to the front support seat.

Then the statics of the car body torsion condition are calculated by using ANSYS, and the results of the deformation are shown in figures 6(a) and 6(b). According to the figure that the maximum stress value of torsion car body is 36.67 MPa. It occurs at the right sill and below the yield strength of the aluminum alloy. So the results meet the strength requirement.
In summary, the designed car body meets the requirements of the frontal strength and stiffness of the car under bending conditions. It guarantees the safety and reliability of the pure electric car.

Dynamic Analysis

Table 3 lists that the frequencies and mode of car body. Figure 7 are the first six modes of car body. The dynamic performance of the object depends mainly on the low order vibration modes in this paper. The main concern in car body design is the minimum number of frequencies that cause the body to resonate. Therefore, the first 6 modes are extracted in modal analysis.

Table 3  The frequencies and mode of the car body

(a) 1st

(b) 2nd
The excitations for pure electric vehicles come from a variety of factors. Road excitation is determined by the condition of the road surface. On urban roads and highways with good road condition, the motivation is generally 1~3Hz, which is negligible. The speed is 50-80km/h on the city road or the speed is 80-120km/h on the highway. The excitation caused by the transmission shaft is large, and the vibration frequency is above 40Hz. In general, the first order frequency of the car body should be in the range of 20~30Hz. The frequency of car body designed is 20.467Hz in this paper, which is located in the normal range.

It is the ability of body structure to resist torsion and bending deformation in the first order torsion and first order bending. The velocity response near frequency 30Hz-40Hz is greater in car body design. This is caused because of the resonance by excitation frequency and first order bending and first order torsion of car body. Therefore, the design requirement of the body is that the first torsion frequency is greater than 30Hz, and the first bending frequency is greater than 40Hz. According to the results of modal analysis, it can be concluded that the design of the body meets the requirements of modal analysis.

Figure 7. The first six modes of car body.

Conclusion
According to the difference of pure electric vehicle and traditional fuel vehicles, taking into account the design of compact and lightweight body structure design in this paper. The author used the finite element analysis method of mechanics based on ANSYS software. The car body structure design and mechanical analysis is carried out to ensure the structural mechanical characteristics of the car body.
