Abstract—Nuclear design could be used for constructing packing and covering of a graph in combinatorial design theory. We generalize the nuclear design to group divisible nuclear design, and discuss the upper bound of block number for group divisible nuclear design with block size 4.

Keywords—group divisible; nuclear design; packing; covering

I. INTRODUCTION

Nuclear design is an important conception in combinatorial design theory. Let H be a simple graph and G be a set of simple graphs. Let λ be a positive integer and λH denote the graph H with each of its edges replicated λ times. Let X be the vertex set of H, we define a (λH; G)-nuclear design as follows:

1. A (λH; G)-packing is a pair \( (X, A) \) where A is a collection of subgraphs (called blocks) of \( λH \), such that each block is isomorphic to a graph of G, and each edge of \( λH \) is contained in at most \( λ \) blocks of \( A \). |A| is as large as possible.

2. A (λH; G)-covering is a pair \( (X, B) \) where B is a collection of subgraphs (called blocks) of \( λH \), such that each block is isomorphic to a graph of G, and each edge of \( λH \) is contained in at least \( λ \) blocks of \( B \). |B| is as small as possible.

3. A (λH; G)-nuclear design is a pair \( (X, C) \) where C is a collection of subgraphs (called blocks) of \( λH \), such that \( C = A \cup B \) and C is as large as possible among all intersections of any maximum A and minimum B.

In this paper, we discuss the situation \( λ = 1 \). When H is the complete graph \( K_v \), a \( (K_v; G) \)-packing is denoted by a P(v; G; 1)

II. THE UPPER BOUND OF BLOCK NUMBER

A (H; G)-packing \( (X, A) \) is called maximum if there does not exist any (H; G)-packing \( (X, A') \) with |A'| > |A|. The leave graph (or leave) of a (H; G)-packing \( (X, A) \) is the graph \( (X, L) \) which is the collection of unused edges. A (H; G)-covering \( (X, B) \) is called minimum if there does not exist any (H; G)-covering \( (X, B') \) with |B'| < |B|. The excess graph (or excess) of a (H; G)-covering \( (X, B) \) is the graph \( (X, E) \) which is the collection of edges with multiplicity more than one. If the leave graph of a (H; G)- packing is null, then such a packing is maximum, and referred to as a (H; G)-design. We always write G-MGDP instead of maximum G-GDP. The packing number of \( D(G, g^2) \) is the number of blocks in a G-MGDP of type \( g^n \).

In this paper, we concern the situation about \( G = K_3 + e \) and \( G = K_4 - e \). \( K_3 + e \) is a graph with vertices a, b, c, d and edges ab, bc, ac, cd, denoted by (a,b,c,d). \( K_4 - e \) is a graph with vertices a, b, c, d and edges ab, ac, ad, bc, bd, denoted by [a,b,c,d].

The upper bound of \( D(K_3 + e, g^2) \) is as follows.

\[ D(K_3 + e, g^2) \leq \left\lfloor \frac{n(n-1)g^2}{8} \right\rfloor \]

If \( D(K_3 + e, g^2) \) could attain \( \left\lfloor \frac{n(n-1)g^2}{8} \right\rfloor \), then number of edges in the leave would be

\[ \frac{n(n-1)g^2}{2} - 4 \left\lfloor \frac{n(n-1)g^2}{8} \right\rfloor = \begin{cases} 0, & n(n-1)g^2 = 0, 1(mod 8), \\ 1, & n(n-1)g^2 = 2, 7(mod 8), \\ 2, & n(n-1)g^2 = 4, 5(mod 8), \\ 3, & n(n-1)g^2 = 3, 6(mod 8). \end{cases} \]

Then the possible leave would be
The upper bound of $D(K_4-e, g^*)$ is as follows.

$$D(K_4-e, g^*) \leq \left\lfloor \frac{n(n-1)g^2}{10} \right\rfloor$$

If $D(K_4-e, g^*) = \left\lfloor \frac{n(n-1)g^2}{10} \right\rfloor$, then number of edges in the leave would be

$$\frac{n(n-1)g^2}{2} - 5 \left\lfloor \frac{n(n-1)g^2}{10} \right\rfloor = \begin{cases} 
0, & n(n-1)g^2 \equiv 0 \pmod{10}, \\
1, & n(n-1)g^2 \equiv 2 \pmod{10}, \\
2, & n(n-1)g^2 \equiv 4 \pmod{10}, \\
3, & n(n-1)g^2 \equiv 6 \pmod{10}, \\
4, & n(n-1)g^2 \equiv 8 \pmod{10}.
\end{cases}$$

Then the possible leave would be

<table>
<thead>
<tr>
<th>$n$</th>
<th>$n \pmod{8}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g \pmod{2}$</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>$\emptyset$</td>
</tr>
<tr>
<td>1</td>
<td>$\emptyset$</td>
</tr>
</tbody>
</table>

In table 1 and 2, $E_i$ is any graph with $i$ edges, for $i=1,2,3,4$. We exhibit all the possible leave graph as follows. For $E_{i,j}$, $i$ is the edge number and $j$ is the serial number.

We denote $N(G, g^*)$ the number of blocks in a G-GDND of type $g^*$. Combine the above discussion and definition, we obtain the following theorem.

**Theorem 2.1** When $G=K_3+e$ and $G=K_4-e$, the upper bound of block number for G-GDND of type $g^*$ as follows:

1. $N(K_3+e, g^*) \leq D(K_3+e, g^*) \leq \left\lfloor \frac{n(n-1)g^2}{8} \right\rfloor$,
2. $N(K_4-e, g^*) \leq D(K_4-e, g^*) \leq \left\lfloor \frac{n(n-1)g^2}{10} \right\rfloor$.
