Abstract—In order to improve the quality of noise signals reconstruction method, an algorithm of adaptive dual gradient projection for sparse reconstruction of compressed sensing theory is proposed. In ADGPSR algorithm, the pursuit direction is updated in two conjugate directions, the better original signals estimated value is computed by conjugate coefficient. Thus the reconstruction quality is improved. Experiment results show that, compared with the GPSR algorithm, ADGPSR improves the reconstruction accuracy, improves PSNR of reconstruction signals, and exhibits higher robustness under different noise intensities.

Keywords—signal processing, gradient projection, compressed sensing, image reconstruction

I. INTRODUCTION

The Nyquist sampling theorem of information theory is the measurement rules of signal sample, which is proposed by the American Electrical Engineer H. Nyquist. In 1928 the founder of information theory C.E. Shannon proves the Shannon sample theory and cites it as a theorem[1,2]. The Shannon sample theory occupy all areas of signal acquisition, image acquisition, processing, storage, transmission, etc. The Shannon sample theory works in the way of that the sampling rate not less than two times the highest frequency[3].

With the development of information technology, there are two question of the Shannon sample theory. The first question is that the data acquisition and processing is difficult in some conditions, such as the ultra-wideband communication system, UWB signal processing, THz imaging, nuclear magnetic resonance, space exploration, and so on. Second question is that the data acquisition and processing is costly in some conditions, such as the ultra-wideband communication system, UWB signal processing, THz imaging, nuclear magnetic resonance, space exploration, and so on. Thus the signal acquisition on the acquisition of equipment is reduced, especially for high resolution acquisition signals, the cost of signal acquisition and processing are saved[5,6].

Point to the reconstruction quality of GPSR algorithm, we propose an ADGPSR algorithm (adaptive dual gradient projection for sparse reconstruction). In ADGPSR when computing the gradient projection directions, we compute two conjugate searching directions. The signals reconstruction quality of ADGPSR is higher than GPSR algorithm. At the same time, the ADGPSR algorithm improves the SPNR of reconstruction image and exhibits higher robustness under different noise intensities.

II. COMPRESSED SENSING THEORY AND IMAGE RECONSTRUCTION METHOD

A. Compressed sensing theory

In compressed sensing theory, the signal must be sparse, or can be represented as sparse by some transforms. In general, the signals are not sparse, after a certain transformation (such as wavelet transform), the signals can be considered to be sparse, for example, after the wavelet transform, the transform results which contain K major results, and other N-K results are set to zero. Assume that the original signal to be processed for \( f \in \mathbb{R}^N \), it's sparse basis is matrix \( \Psi \), in this way the signal \( f \) is sparse on the base \( \Psi \), this process can be expressed as formula (1):

\[
\mathbf{f} = \mathbf{\Psi} x
\]

where \( x \) is the decomposition of the system, it has a sparse features as formula (2):

\[
\left\| x \right\|_0 \leq k
\]

The symbol \( \left\| x \right\|_0 \) is the norm of signal \( l_0 \), a number of non-zero value vector. After the signal is sparse representation, the random measurement can be complete by an observation matrix as formula (3):

\[
\mathbf{y} = \mathbf{\Phi f} = \mathbf{\Phi \Psi x} = \mathbf{Ax}
\]

where \( y \) is the measurement vector, \( y \in \mathbb{R}^M \), \( M << N \), because the signal has a sparse, the decoding...
process of the above-mentioned problems can be solved by the following formula:

$$\min \| x \|_1 \text{ s.t. } y = Ax \quad (4)$$

When the coefficient vectors are get, the signal $f$ can be restored by $f = \Psi x$.

However, formula (4) is a NP-hard problem, it can’t be solved within a limited time. One of the most important contribution of the compressed sensing theory is that the question of norm $l_0$ and equal to question norm $l_1$, when the signals are sparse and the observation matrix satisfy certain conditions.

$$\min \| x \|_1 \text{ s.t. } y = Ax \quad (5)$$

The symbol $\| x \|_1$ indicates that norm of $l_1$, the absolute value of the vector. Solving problems of the norm is a convex optimization problem, can be resolved by linear programming.

### B ADGPSR reconstruction method

In the actual measurement process noise will be introduced inevitably, the model can be expressed as:

$$y = Ox + n \quad (6)$$

Where $n$ is the measurement noise vector. In this case, the signal reconstruction process can be expressed as:

$$\min \| x \|_1 \text{ subject to } \| y - Ax \|_2 \leq \varepsilon \quad (7)$$

The algorithm, developed from the damped Newton method, for an unconstrained optimization of smooth nonlinear function $F$, it is every step of the formula

$$\delta^{(k)} = -H_k^{-1}F(z^{(k)}) \quad (8)$$

Because the $H_k$ can not be calculated, need to figure out:

$$\nabla F(z^{(k)}) - \nabla F(z^{(k-1)}) \approx \eta_k \left[ z^{(k)} - z^{(k-1)} \right] \quad (9)$$

Approximation algorithm of $H_k$ is not satisfied, increase of algorithm iterations.

$$\min c^T z + \frac{1}{2} z^T B z = F(z) \quad (10)$$

Where, 

$$z = \begin{bmatrix} u \\ v \end{bmatrix}, \quad b = A^T y, \quad c = \tau 1_{2n} + \begin{bmatrix} -b \\ 0 \end{bmatrix}, \quad B = \begin{bmatrix} A^T A & -A^T \\ -A^T A & A^T A \end{bmatrix}, \quad u \text{ and } v,$$

corresponding to the positive and negative part of the vector $x, x = u - v, \ u \geq 0, \ v \geq 0, \ 1_{2n} 2n$-dimensional unit column vector.

The realizing process of ADGPSR as follows:

**Step 1**: Choose parameters

$$\alpha_{\min}, \alpha_{\max}, \alpha_0 \in [\alpha_{\min}, \alpha_{\max}], \text{ set } k = 0.$$

Then, According to the formula (X) compute $\alpha_0$

$$\alpha_0 = -\frac{(g^{(k)})^T g^{(k)}}{(g^{(k)})^T B g^{(k)}} \quad (11)$$

**Step 2**: Compute step

$$\delta^{(k)} = (z^{(k)} - \alpha^{(k)} \nabla f(z^{(k)})) - \alpha^{(k-1)} \nabla f(z^{(k-1)}) \quad (12)$$

**Step 3**: Search $\chi^{(k)} \in [0,1]$ in the interval to a minimum $\chi^{(k)}$, and set

$$z^{(k+1)} = z^{(k)} + \lambda_1^{(k)} \delta^{(k)} + \lambda_2^{(k-1)} \delta^{(k-1)} \quad (13)$$

Approximation $z^{(k+1)}$ solution then the algorithm terminates, $z^{(k+1)}$ is the reconstructed image, otherwise look for $\chi^{(k)}$.

$$\alpha_1^{(k)} = \frac{\nabla f(z^{(k)}), \quad \alpha_1^{(k-1)} = \frac{\nabla f(z^{(k-1)}))}{\| \delta^{(k)} \|_2, \| \delta^{(k-1)} \|_2} \quad (14)$$

Where, $c^{(k)}$ is the vector $c^{(k)} = \nabla F(z)$

The parameter $\gamma^{(k)}$ is compute as follows,

$$\gamma^{(k)} = (\delta^{(k)})^T B \delta^{(k)}$$

Where,

$$\gamma_{1,2}^{(k)} = \text{mid}\{0, (\delta^{(k)})^T B \delta^{(k)}, 1\} \quad (15)$$

The parameter $F(z)$ is compute as follows,

$$F(z) = \min c^T z + \frac{1}{2} z^T B z \quad (16)$$

Where value of $z = \begin{cases} 1 & \text{if } z_{(j)} > 0 \\ -1 & \text{if } z_{(j)} < 0 \end{cases}$

$$j = 1, 2, \ldots, k \quad z_{(j)} \text{ is the reconstruction vector}$$

In the ADGPSR method, we compute the gradient direction of $z^{(k)}$ and the step length of $\delta_t$ and $\delta_2$, thus we can select the gradient direction of $z^{(k)}$, in order to reduce the alternately search, thus the run time is reduced.

We choose the negative direction of $z^{(k)}$ and $z_{(k-1)}$ firstly, if the termination is reached, the algorithm stops, otherwise, we choose the positive direction of $z^{(k)}$ and $z_{(k-1)}$.

III. EXPERIMENT RESULTS AND ANALYSIS

A Signal reconstruction Test

In the first experiment, we set original signals length is 1024, observation matrix is \( k \times n \) gauss random matrix, k=256 is the length of observation vector. There are 40 random \( \pm 1 \) spikes, In ADGPSR algorithm, the \( \chi_k \equiv 1, \alpha_{\min} = 10^{-30}, \alpha_{\max} = 10^{30}.\tau = 0.005. \)

The original signals and reconstruction signals are shown in Figure1. Experiment results show that, the MES of ADGPSR algorithm is lower than the GPSR algorithm.

![Figure 1: MSE of original signals and reconstruction signals](image)

B Image reconstruction Test

We know that the image is not sparse itself, in this article, we use the wavelet transform sparse the signal. And the random Gaussian matrix as the observation matrix, the variance distribution \((0,1/N)\). The reconstruction algorithm uses the ADGPSR(Adaptive Gradient Projection for Sparse Reconstruction).

We use the GOLDHILL and RICE image to test the efficient of ADGPSR algorithm, the image size is \(256 \times 256\) and \(512 \times 512\) differently, at the same time we use GPSR algorithm reconstruction image. The figure 2 shows the GOLDHILL image test results. figure 2(a) is the original GOLDHILL image, figure 2(b) is the noise GOLDHILL image with noise variance equals to 2, figure 2(c) is the ADGPSR reconstruction results from noise image, figure 2(d) is the GPSR reconstruction results from noise image. With the same input noise image the GPSR method PSNR is 25.83, the GPSR method PSNR is 22.78.

To compute the PSNR, the block first calculates the mean-squared error using the following equation formula(17),

\[
MSE = \frac{\sum_{M,N} \left[ I_1(m,n) - I_2(m,n) \right]^2}{M \times N}
\]

We compute the PSNR with the follows formula(18),

\[
PSNR = 10 \log_{10} \left( \frac{R^2}{MSE} \right)
\]

![Figure 2: GOLDHILL image and reconstruction results](image)

(c) ADGPSR results (PSNR=25.83) (d) GPSR results (PSNR=22.78)

In order to test the adaptability of the ADGPSR reconstruction algorithm, we use the RICE image to test. Figure 3(a) is the original RICE image, figure 3(b) is the
noise RICE image with noise variance equals to 2, figure 3(c) is the ADGPSR reconstruction results from noise image, figure 3(d) is the GPSR reconstruction results from noise image. With the same input noise image the ADGPSR method PSNR is 16.37, the GPSR method PSNR is 14.07.

IV. SUMMARY

In this paper, ADGPSR algorithm (adaptive dual gradient projection for sparse reconstruction) is proposed, in ADGPSR algorithm when compute the gradient projection of we compute two conjugate direction of pursuit. The signals reconstruction quality of ADGPSR is higher than GPSR algorithm. We test the ADGPSR with non-zero signals and noise image of RICE and GOLDHILL, Compared with GPSR algorithm, the reconstruction quality be enhanced. The PSNR is improved 2~3dB.
